Cristel Pelsser

 UCLouvain

Cyber  
**Excellence**  
by  
Cyberwal

Focus on the inter-domain  
routing protocol  
BGP

The Internet is composed of **Autonomous Systems (AS)**: one or more networks under the control of a single entity.

The Internet is composed of **Autonomous Systems (AS)**: one or more networks under the control of a single entity.

Prefixes of the AS are advertised to the outside using BGP.

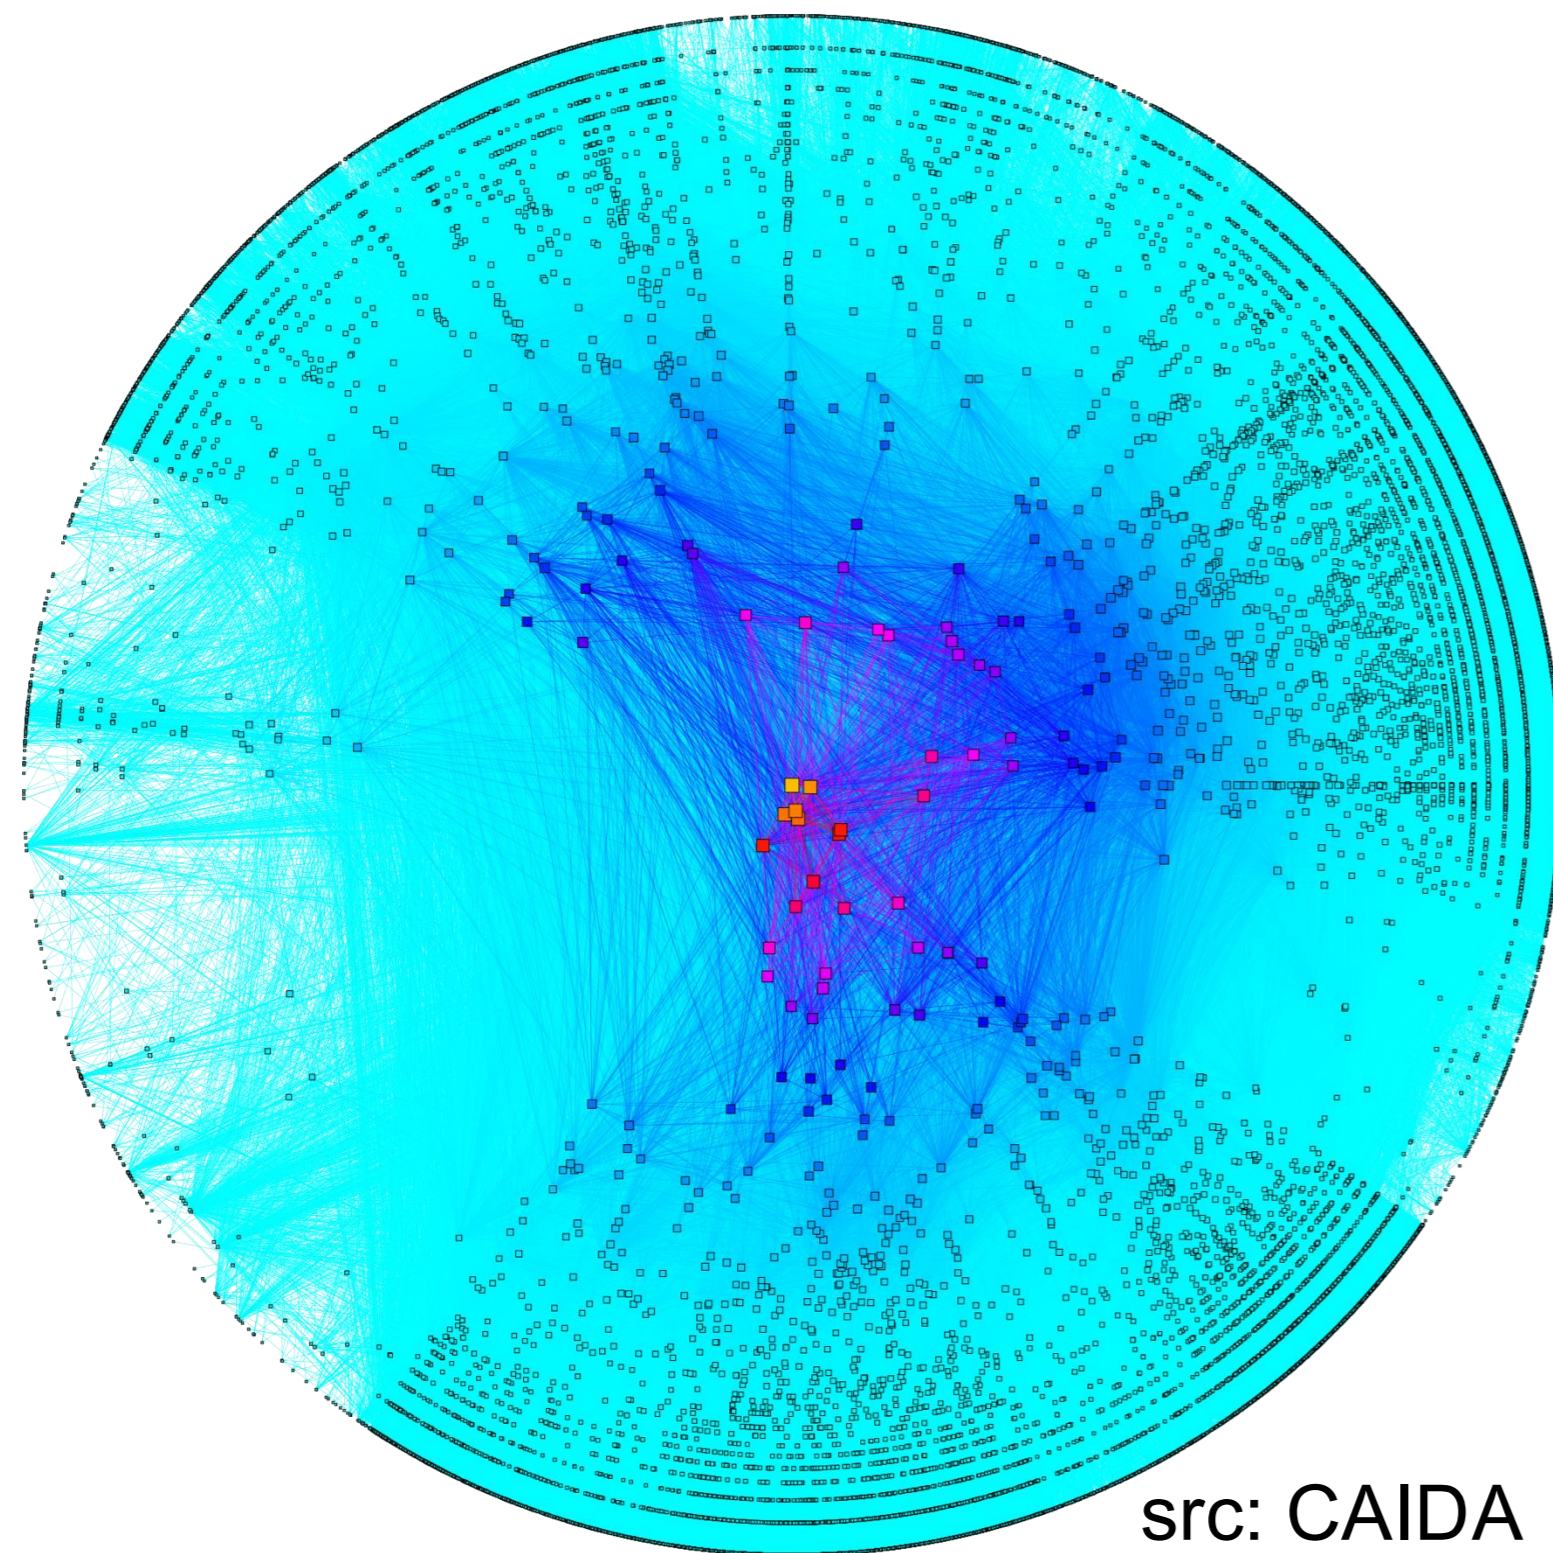

The Internet is composed of **Autonomous Systems (AS)**: one or more networks under the control of a single entity.

Prefixes of the AS are advertised to the outside using BGP.

Traffic flows in the reverse direction.

# The Internet is complex and dynamic

The internet is composed of more than **75 000** ASes

The **routes** in the Internet are computed automatically thanks to the **BGP routing protocol**

# Some vulnerabilities of BGP

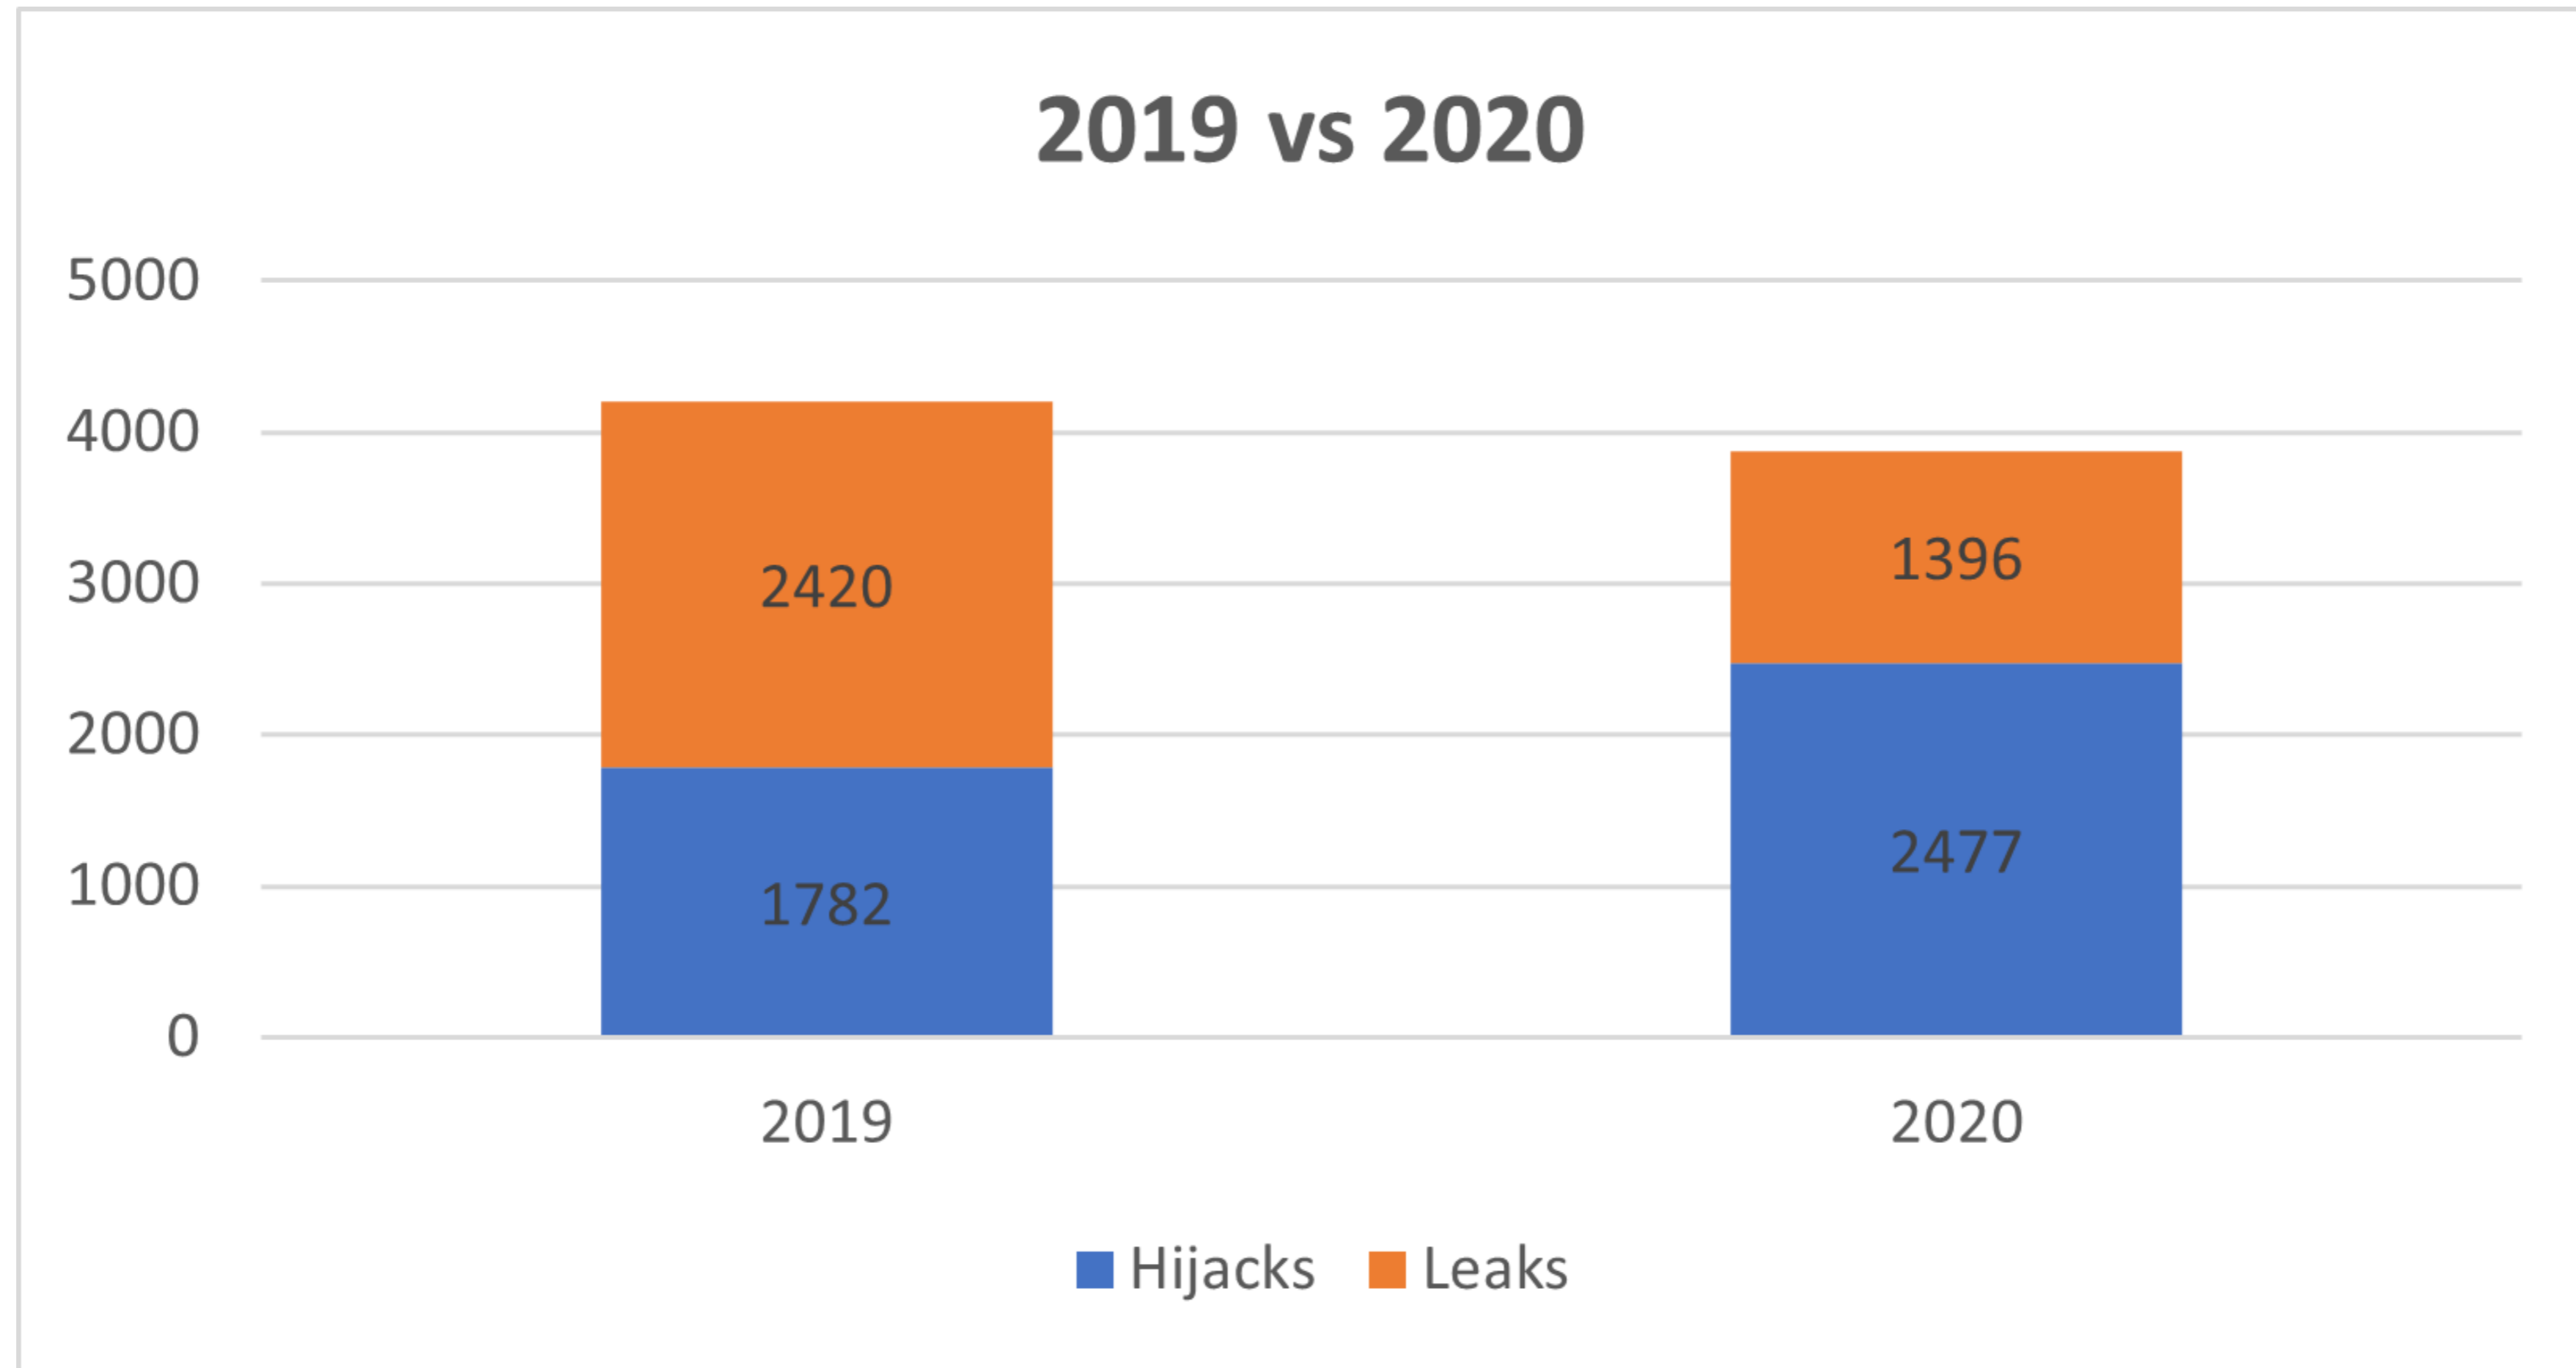

Prefix hijacks

Blackjack attacks

BGP lies

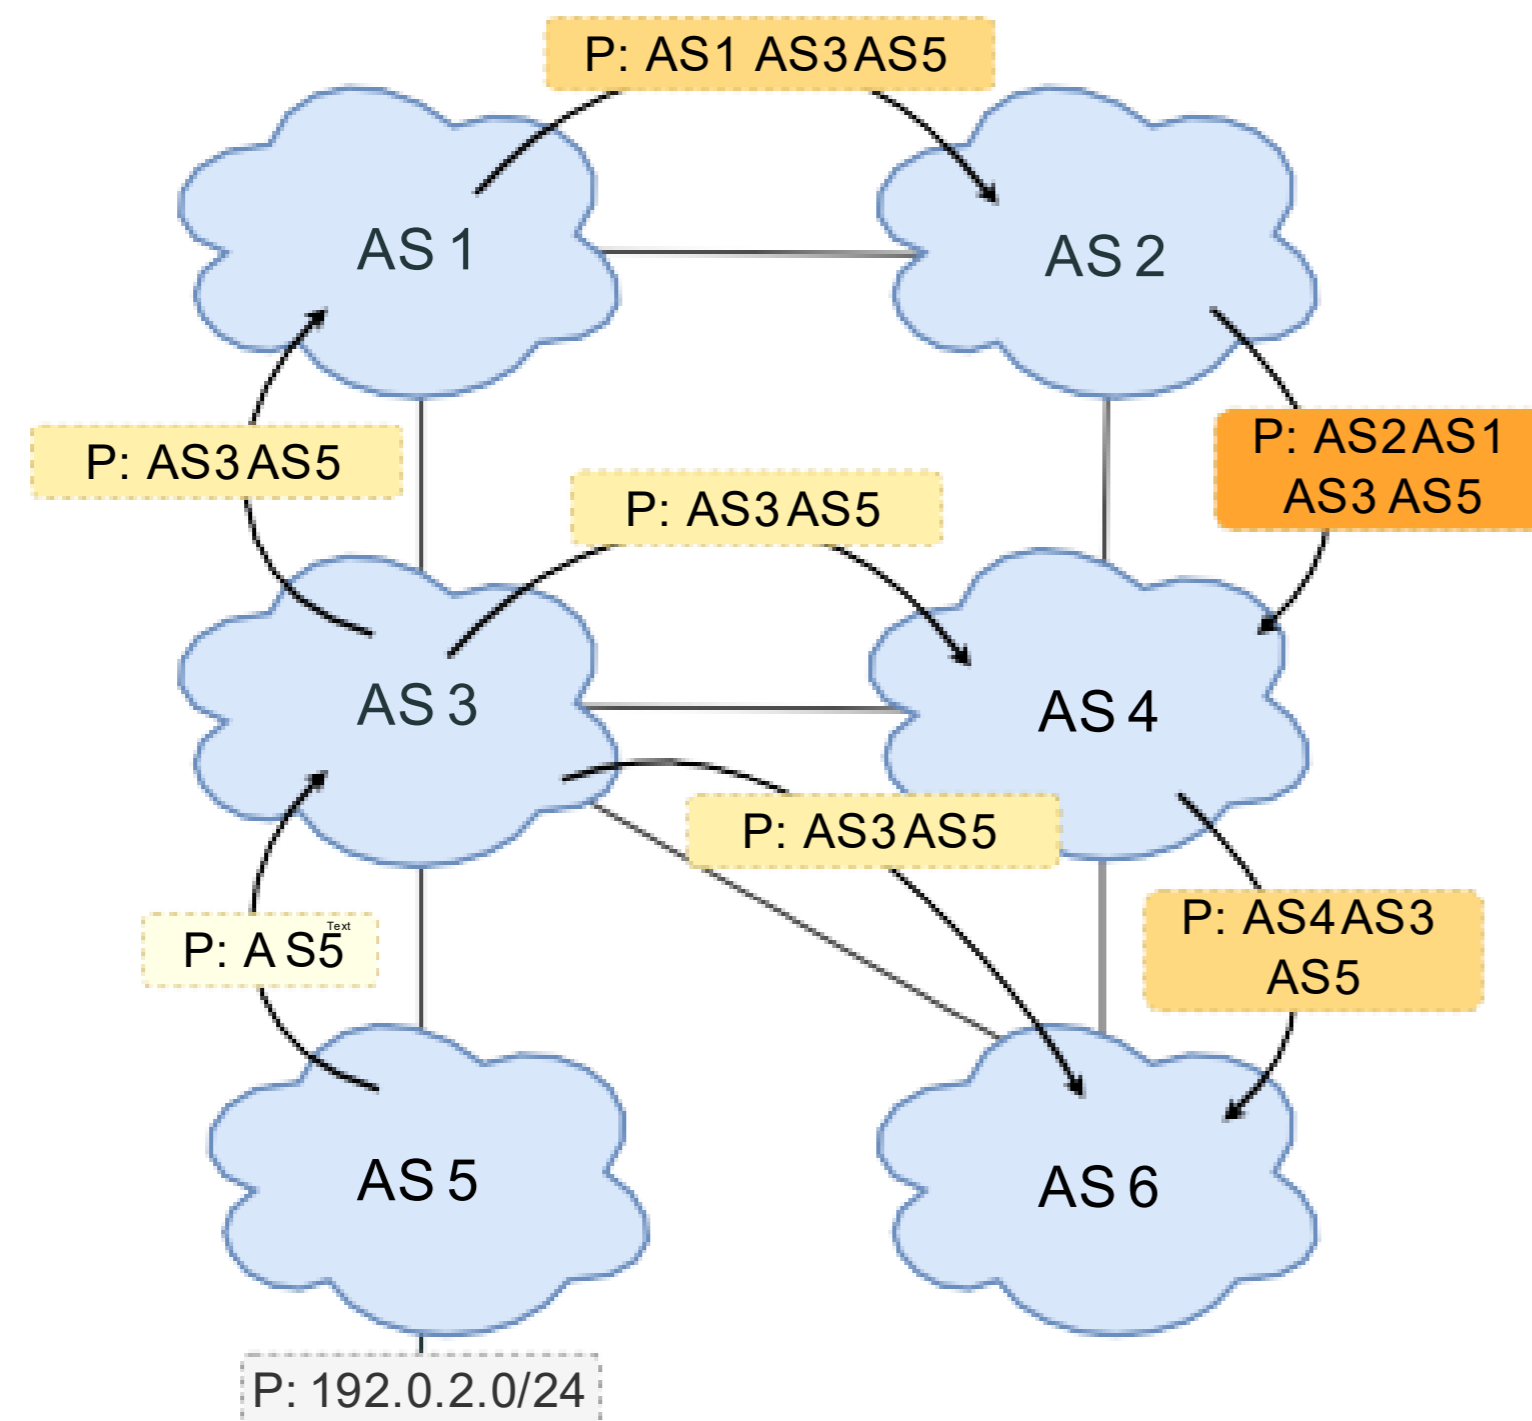

BGP session injection

# There is little to no security in the routing protocol used in the Internet

## Configuration Issue Penalizing Single-Digit ASNs

By Aftab Siddiqui • 23 Jun 2022

[https://www.manrs.org/2022/06/configuration-issue-penalizing-single-digit-asns/?utm\\_source=rss&utm\\_medium=rss&utm\\_campaign=configuration-issue-penalizing-single-digit-asns](https://www.manrs.org/2022/06/configuration-issue-penalizing-single-digit-asns/?utm_source=rss&utm_medium=rss&utm_campaign=configuration-issue-penalizing-single-digit-asns)

# Extract from the blog post:

“In recent years, we’ve noticed that single-digit ASNs (ASN1 through ASN9) often appear to be route hijackers. Is this true? We dug into the data and ultimately realized **no, single-digit ASNs are not hijacking address space at an alarming rate.** What’s happening is the result of a misconfiguration issue because of the “AS path prepend” command on Mikrotik routers.”

[https://www.manrs.org/2022/06/configuration-issue-penalizing-single-digit-asns/?utm\\_source=rss&utm\\_medium=rss&utm\\_campaign=configuration-issue-penalizing-single-digit-asns](https://www.manrs.org/2022/06/configuration-issue-penalizing-single-digit-asns/?utm_source=rss&utm_medium=rss&utm_campaign=configuration-issue-penalizing-single-digit-asns)

# Some vulnerabilities of BGP

Prefix hijacks

**Blackjack attacks**

BGP lies

BGP session injection

A Backjack attack surfs on the blackholing mechanism provided to protect against DDoS

# DDoS are frequent

## DDoS attacks by year and type

As of October 2025

<https://blog.cloudflare.com/ddos-threat-report-2025-q3/>

# DDoS

In a denial of service attack, the infractucture may be congested.

# BGP blackholing

**Blackholing** is a **DDoS mitigation** technique signaled via **BGP** using a community.

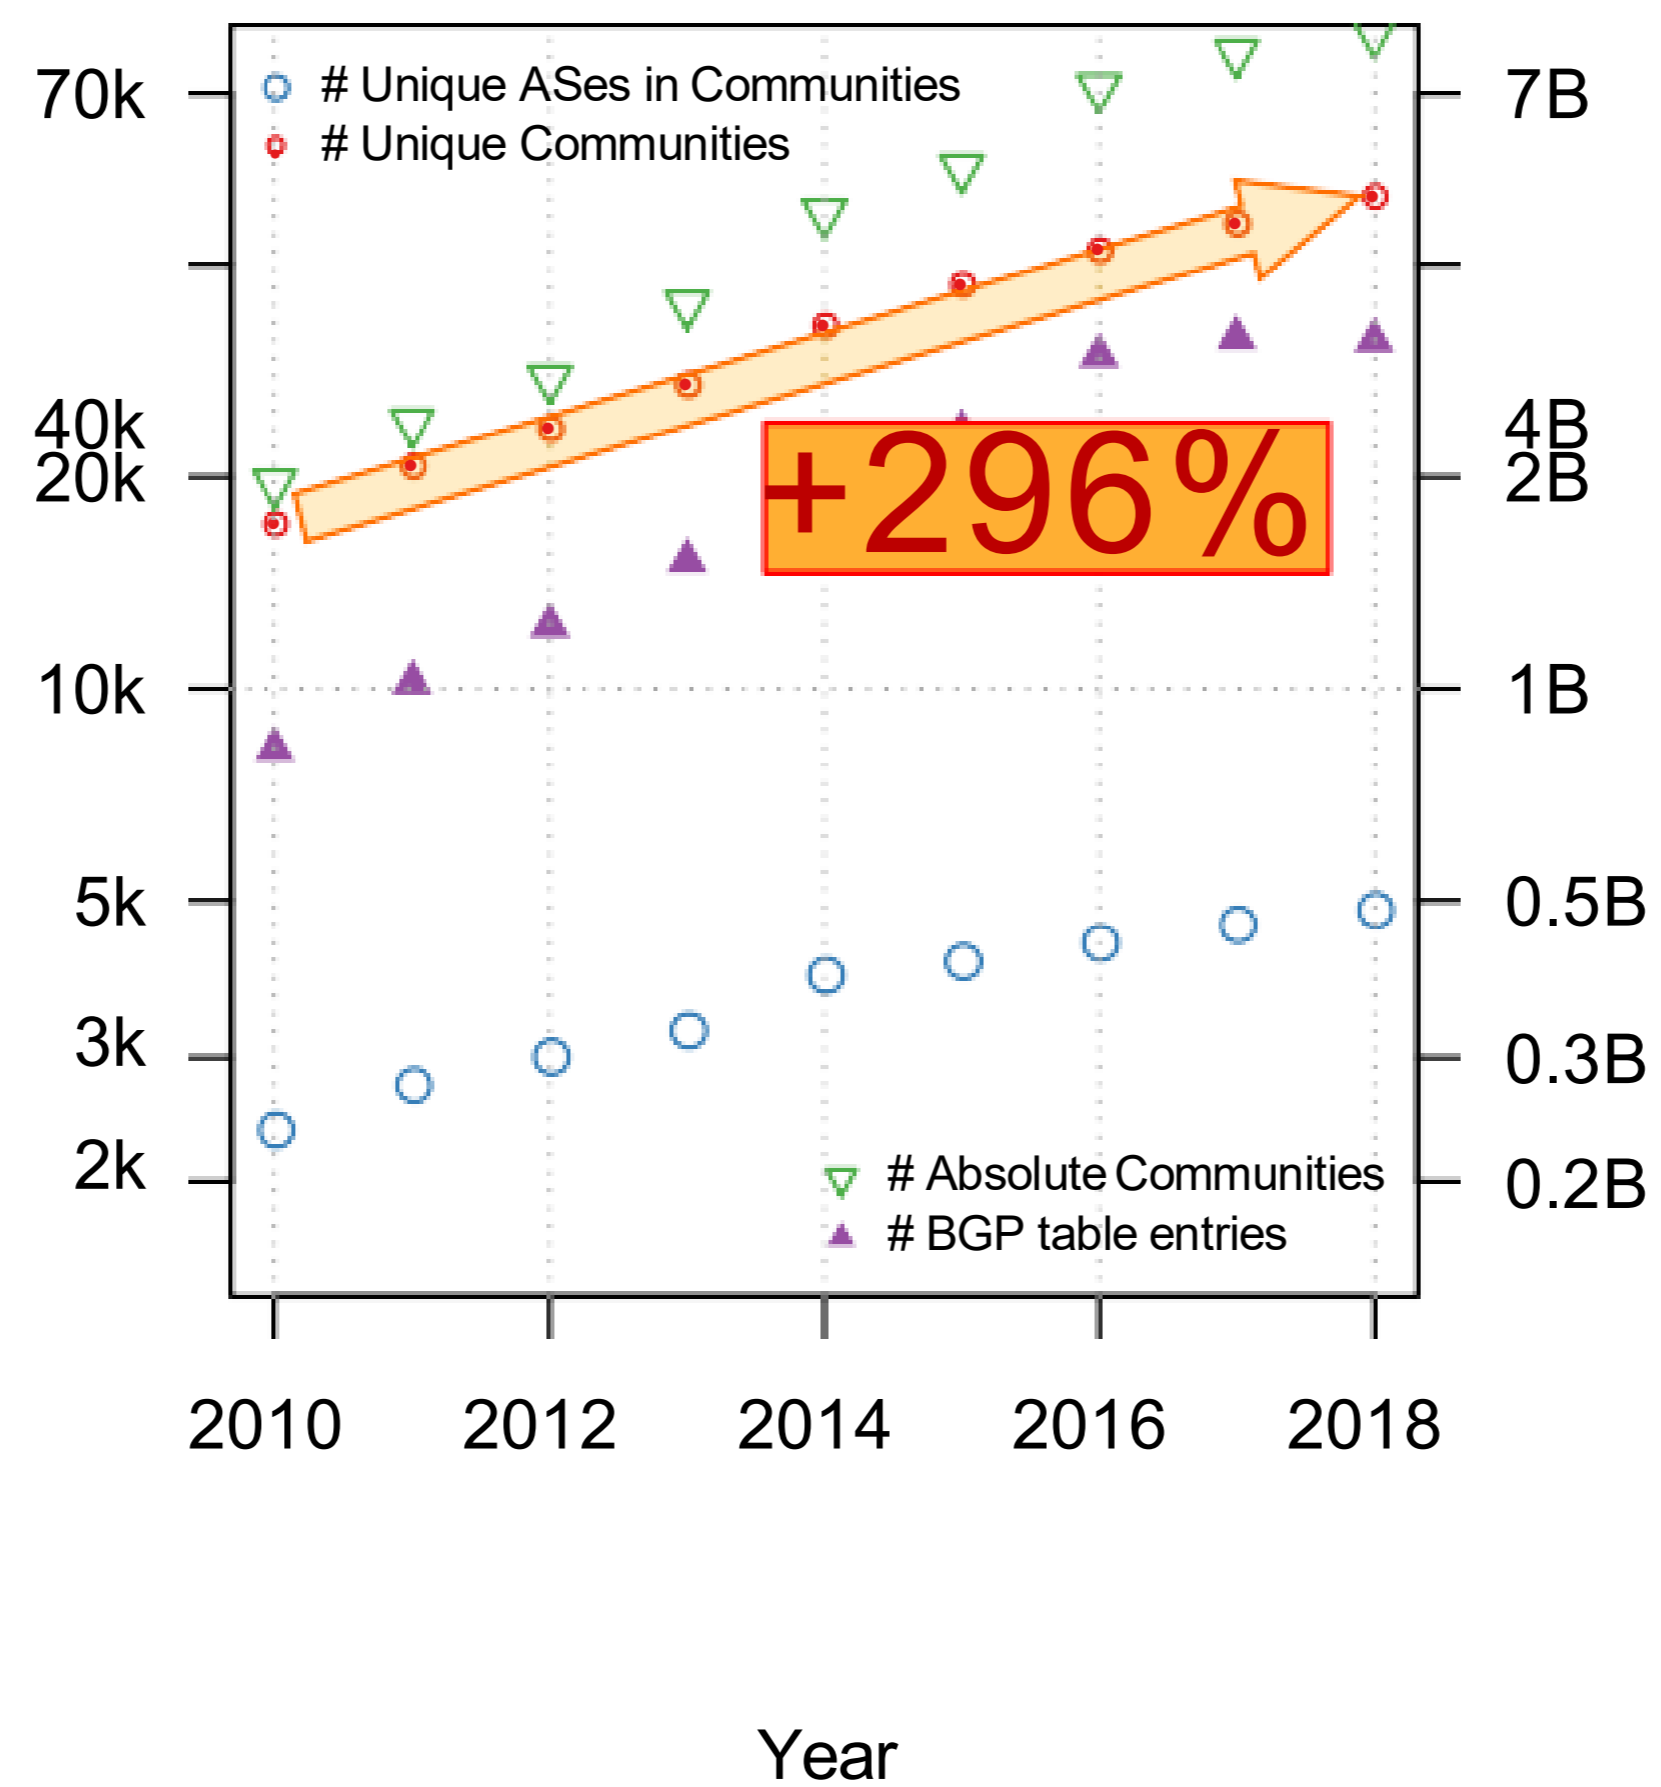

# BGP blackholing

Blackholing is a **DDoS mitigation** technique signaled via **BGP** using a community.

Blackholing has a double-edged sword effect: **all** traffic is dropped.

# BGP community usage is increasing

**Increasing usage warrants a closer look.**

Given the **increasing popularity** of BGP communities  
and the ability to **trigger actions**, the first question that comes  
to the mind of an Internet measurement researcher is. . .

**What could possibly go wrong?**

# Hijack-0 and Blackjack-0

Sermpezis 2018 (Artemis)

## Hijack type-0

AS2 and AS4 traffic is de-routed to AS6 because the advertised path is shorter.

# Hijack-0 and Blackjack-0

Sermpezis 2018 (Artemis)

## Hijack type-0

AS2 and AS4 traffic is

de-routed to AS6 because the advertised path is shorter.

Miller et Pelsser 2019

## Blackjack type-0

All traffic to  $P$  is blackholed at AS3.

**Hijacking + blackholing**

# Best practices for legitimate blackholing empower blackjacks

## Best Practices for blackholing<sup>4</sup>

Give a **higher priority** to blackholing.

Do **not propagate** the advertisement across AS borders.

---

<sup>4</sup>Cisco, [Remotely Triggered Black Hole Filtering - Destination Based and Source Based.](#)

# Best practices for legitimate blackholing empower blackjacks

## Best Practices for blackholing<sup>4</sup>

Give a **higher priority** to blackholing.

Do **not propagate** the advertisement across AS borders.

## Consequences

**Reach:** Precedence over AS path length. Even ASes far away are vulnerable.

**Stealth:** The attacker is not dropping traffic himself.

---

<sup>4</sup>Cisco, [Remotely Triggered Black Hole Filtering - Destination Based and Source Based](#).

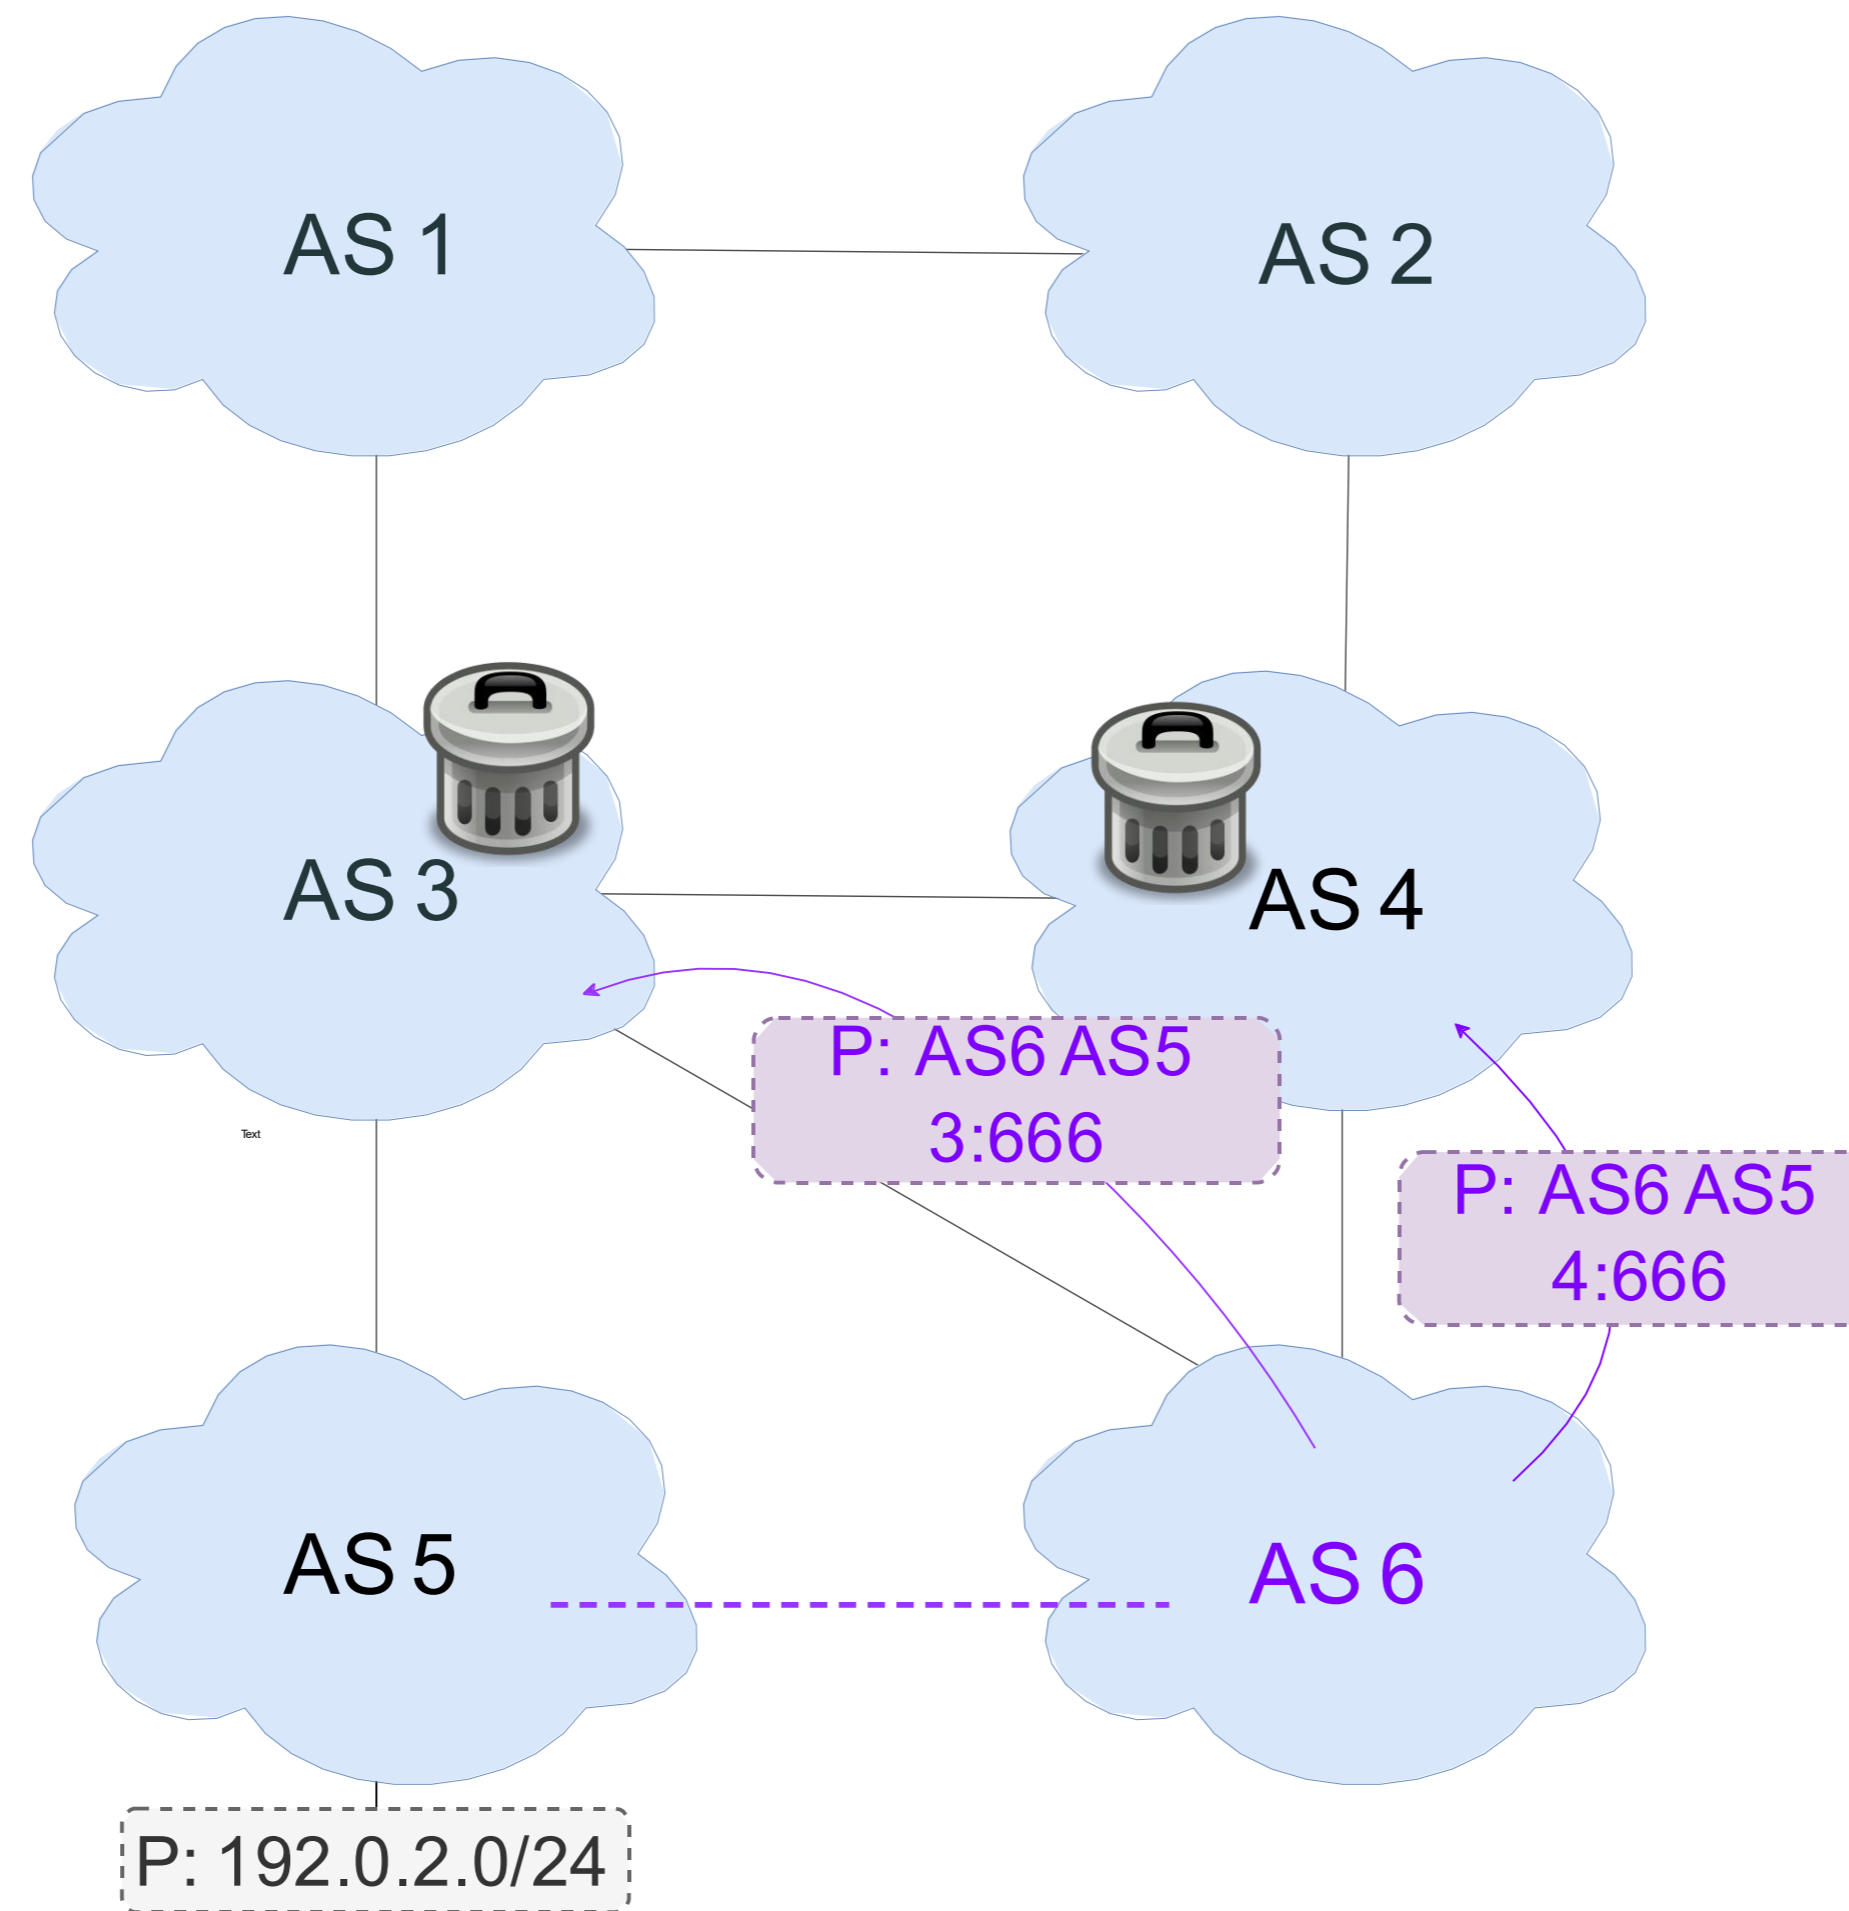

# How to prevent mis-origination?

**ROA** Route Origin Authorizations are digitally signed objects attesting that a given AS is **authorized to originate** routes for a set of prefixes.

**ROV** With Route Origin validation, an AS **validates the origin** of the BGP updates with regard to the content of the RPKI Objects.

**But other attacks are possible.**

# BGP Blackjacks - Type-N

The origin AS is legit. The AS-path is not.

# BGPsec<sup>5</sup>

BGPsec allows ASes to **sign** advertisements.

This guarantees the AS path reflects the **actual path** the advertisement went through.

**But on-paths attacks are still possible.**

# Some vulnerabilities of BGP

Prefix hijacks

Blackjack attacks

BGP lies

BGP session injection

# BGP runs on top of TCP

TCP is vulnerable to injection attacks

The attacker

- guesses the next sequence number
- sends a packet with the sequence number and forged content

The client accepts the content if it arrives before the legit packet

The recommendation is to use MD5 for session authentication.

- But there are tools able to provide payload for a given MD5 digest  
<https://github.com/DavidBuchanan314/monomorph>
- The adoption status of TCP Authentication Option (TCP-AO) for BGP is not known

## KlaySwap crypto users lose funds after BGP hijack

Hackers have stolen roughly \$1.9 million from South Korean cryptocurrency platform **KLAYswap** after they pulled off a rare and clever BGP hijack against the server infrastructure of one of the platform's providers.

The BGP hijack—which is the equivalent of hackers hijacking internet routes to bring users on malicious sites instead of legitimate ones—hit **KakaoTalk**, an instant messaging platform popular in South Korea.

The attack took place earlier this month, on February 3, lasted only for two hours, and KLAYswap has **confirmed** the incident last week and is currently **issuing compensation** for affected users.

**Celer** CelerNetwork  
@CelerNetwork · Follow

 We are seeing reports that reflects potential DNS hijacking of cbridge frontend. We are investigating at the moment and please do not use the frontend for bridging at the moment.

Both attacks are the result of a forged-origin hijack

# ***DFOH***: A System to **Detect Forged-Origin BGP Hijacks** on the **Whole Internet**

# Outline

***DFOH's main challenge***

***DFOH's inference pipeline***

***DFOH's inferences are accurate***

***DFOH is up and running***

# Outline

***DFOH***'s main challenge

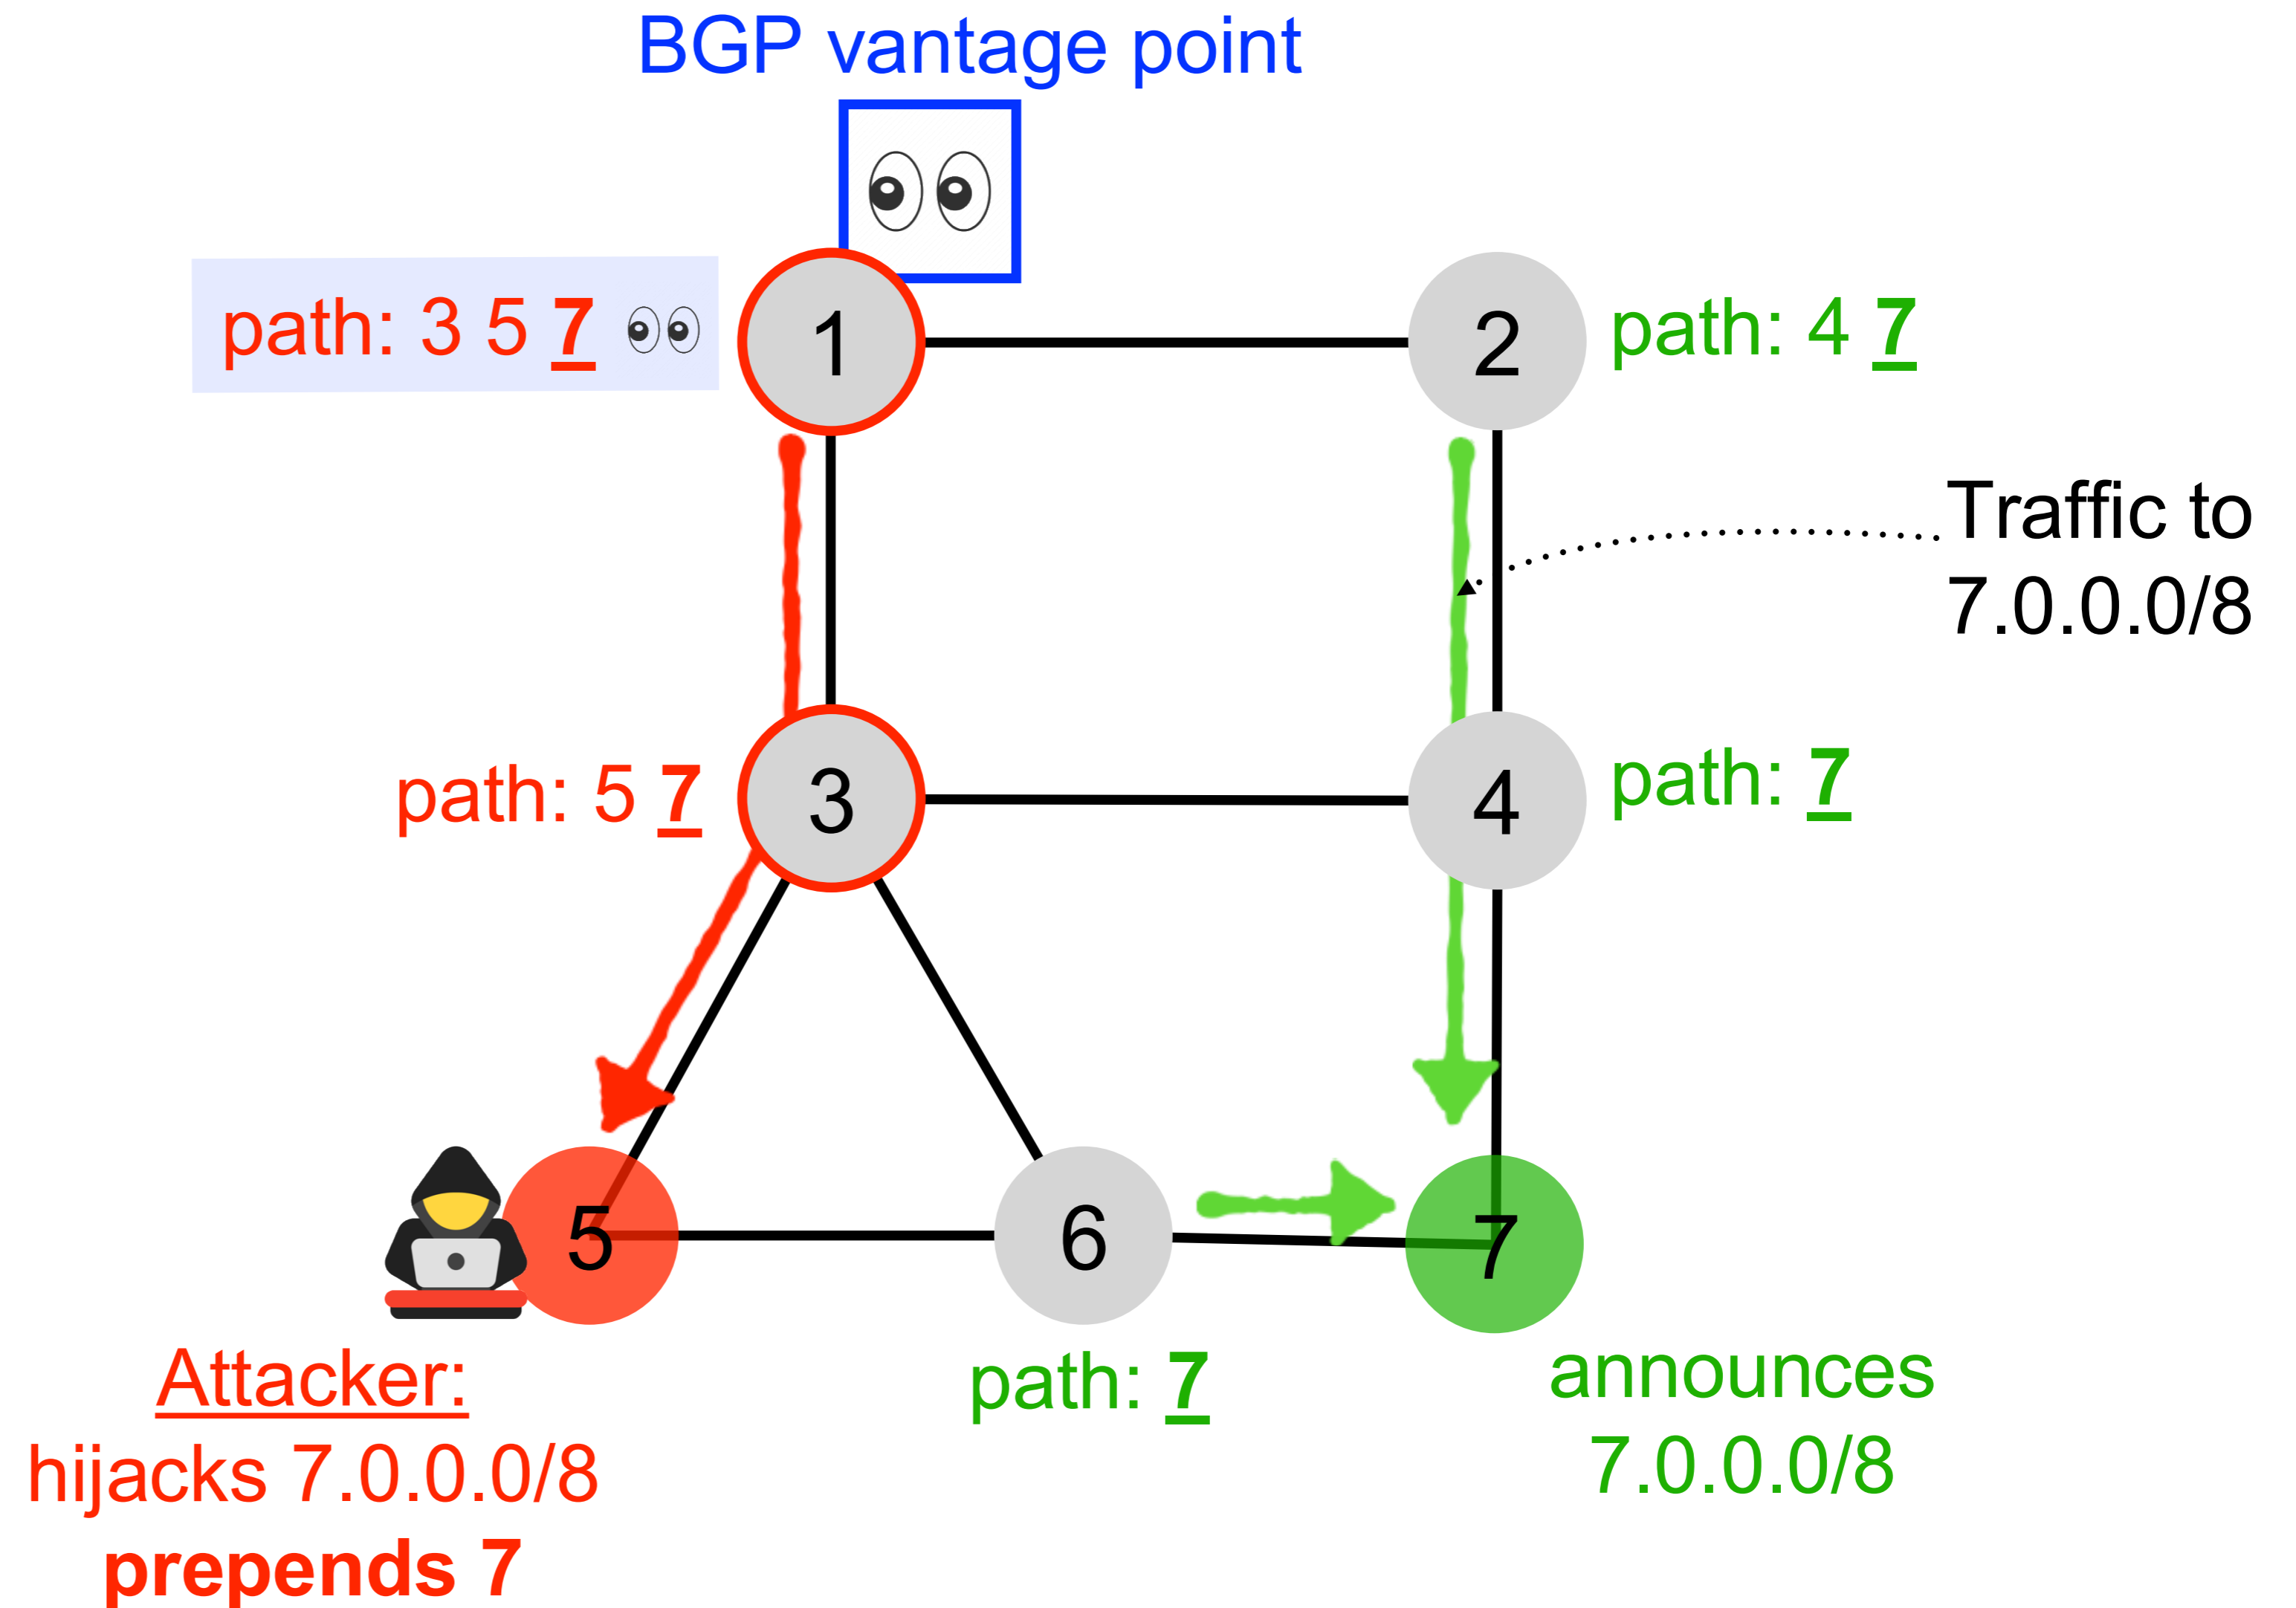

is to detect **fake** AS links

***DFOH***'s inference pipeline

***DFOH***'s inferences are accurate

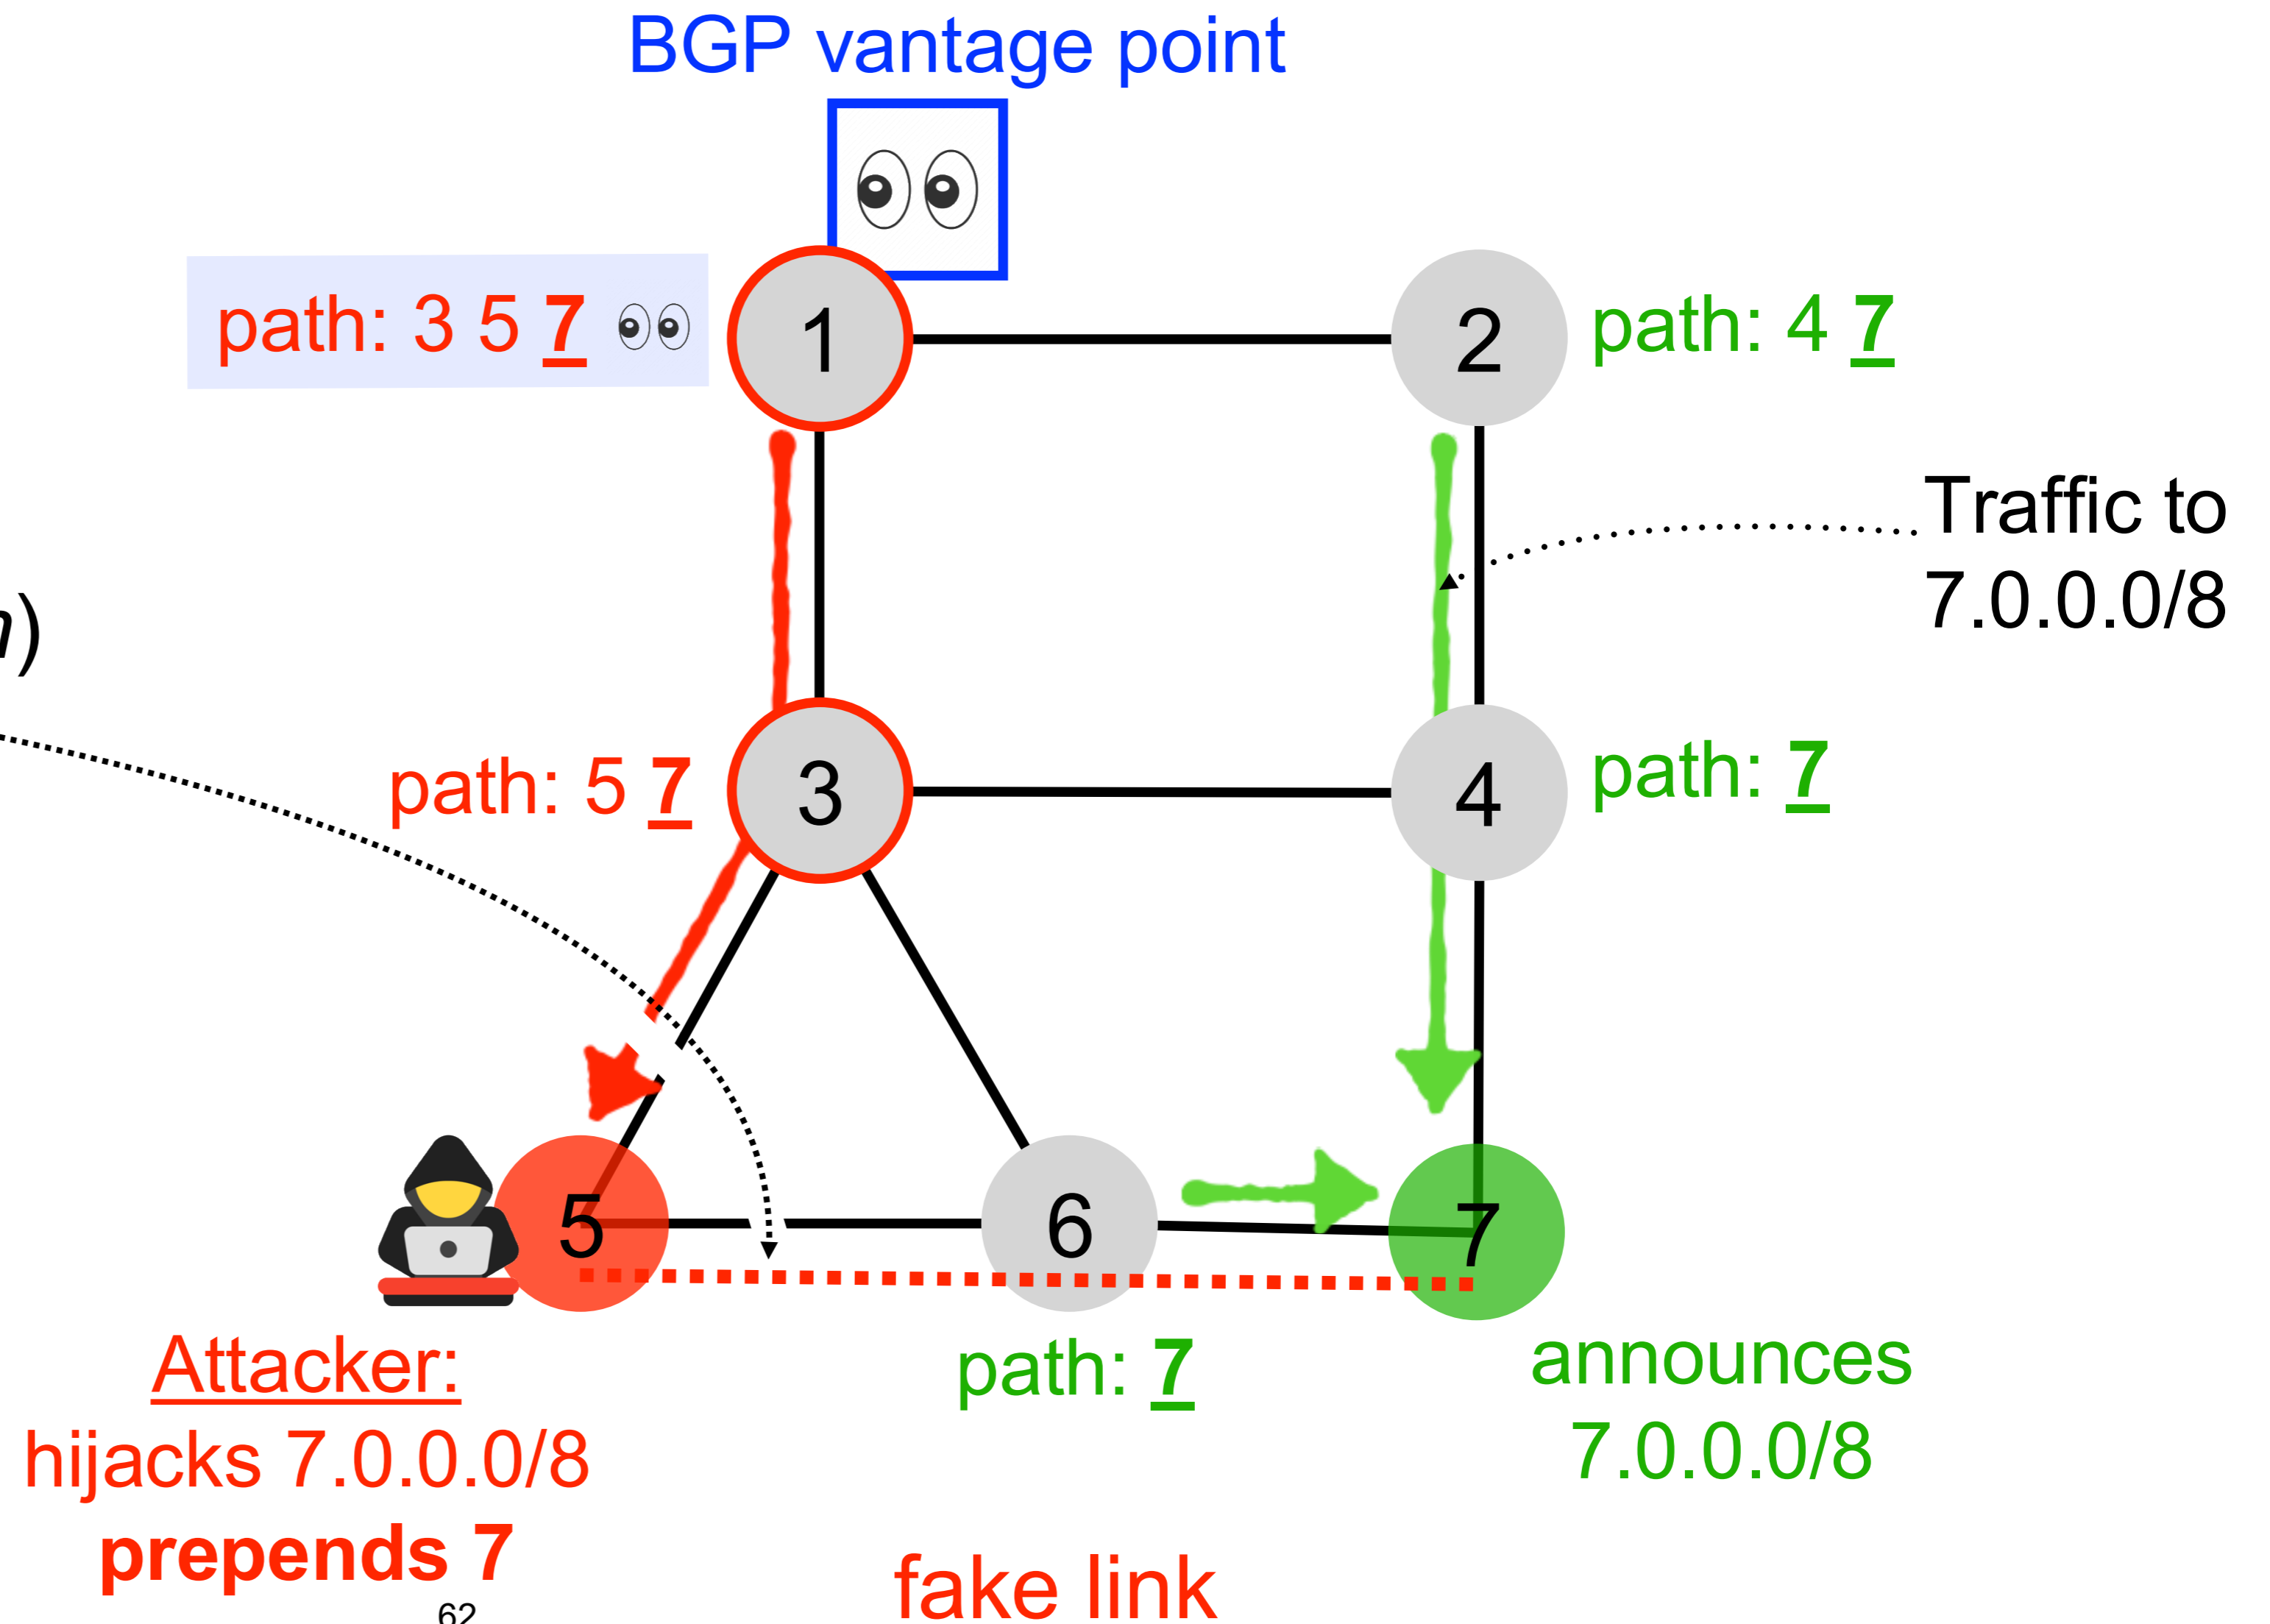

***DFOH*** is up and running

**DFOH** aims to detect the **fake** AS links induced by forged-origin hijacks

**DFOH** aims to detect the **fake** AS links induced by forged-origin hijacks

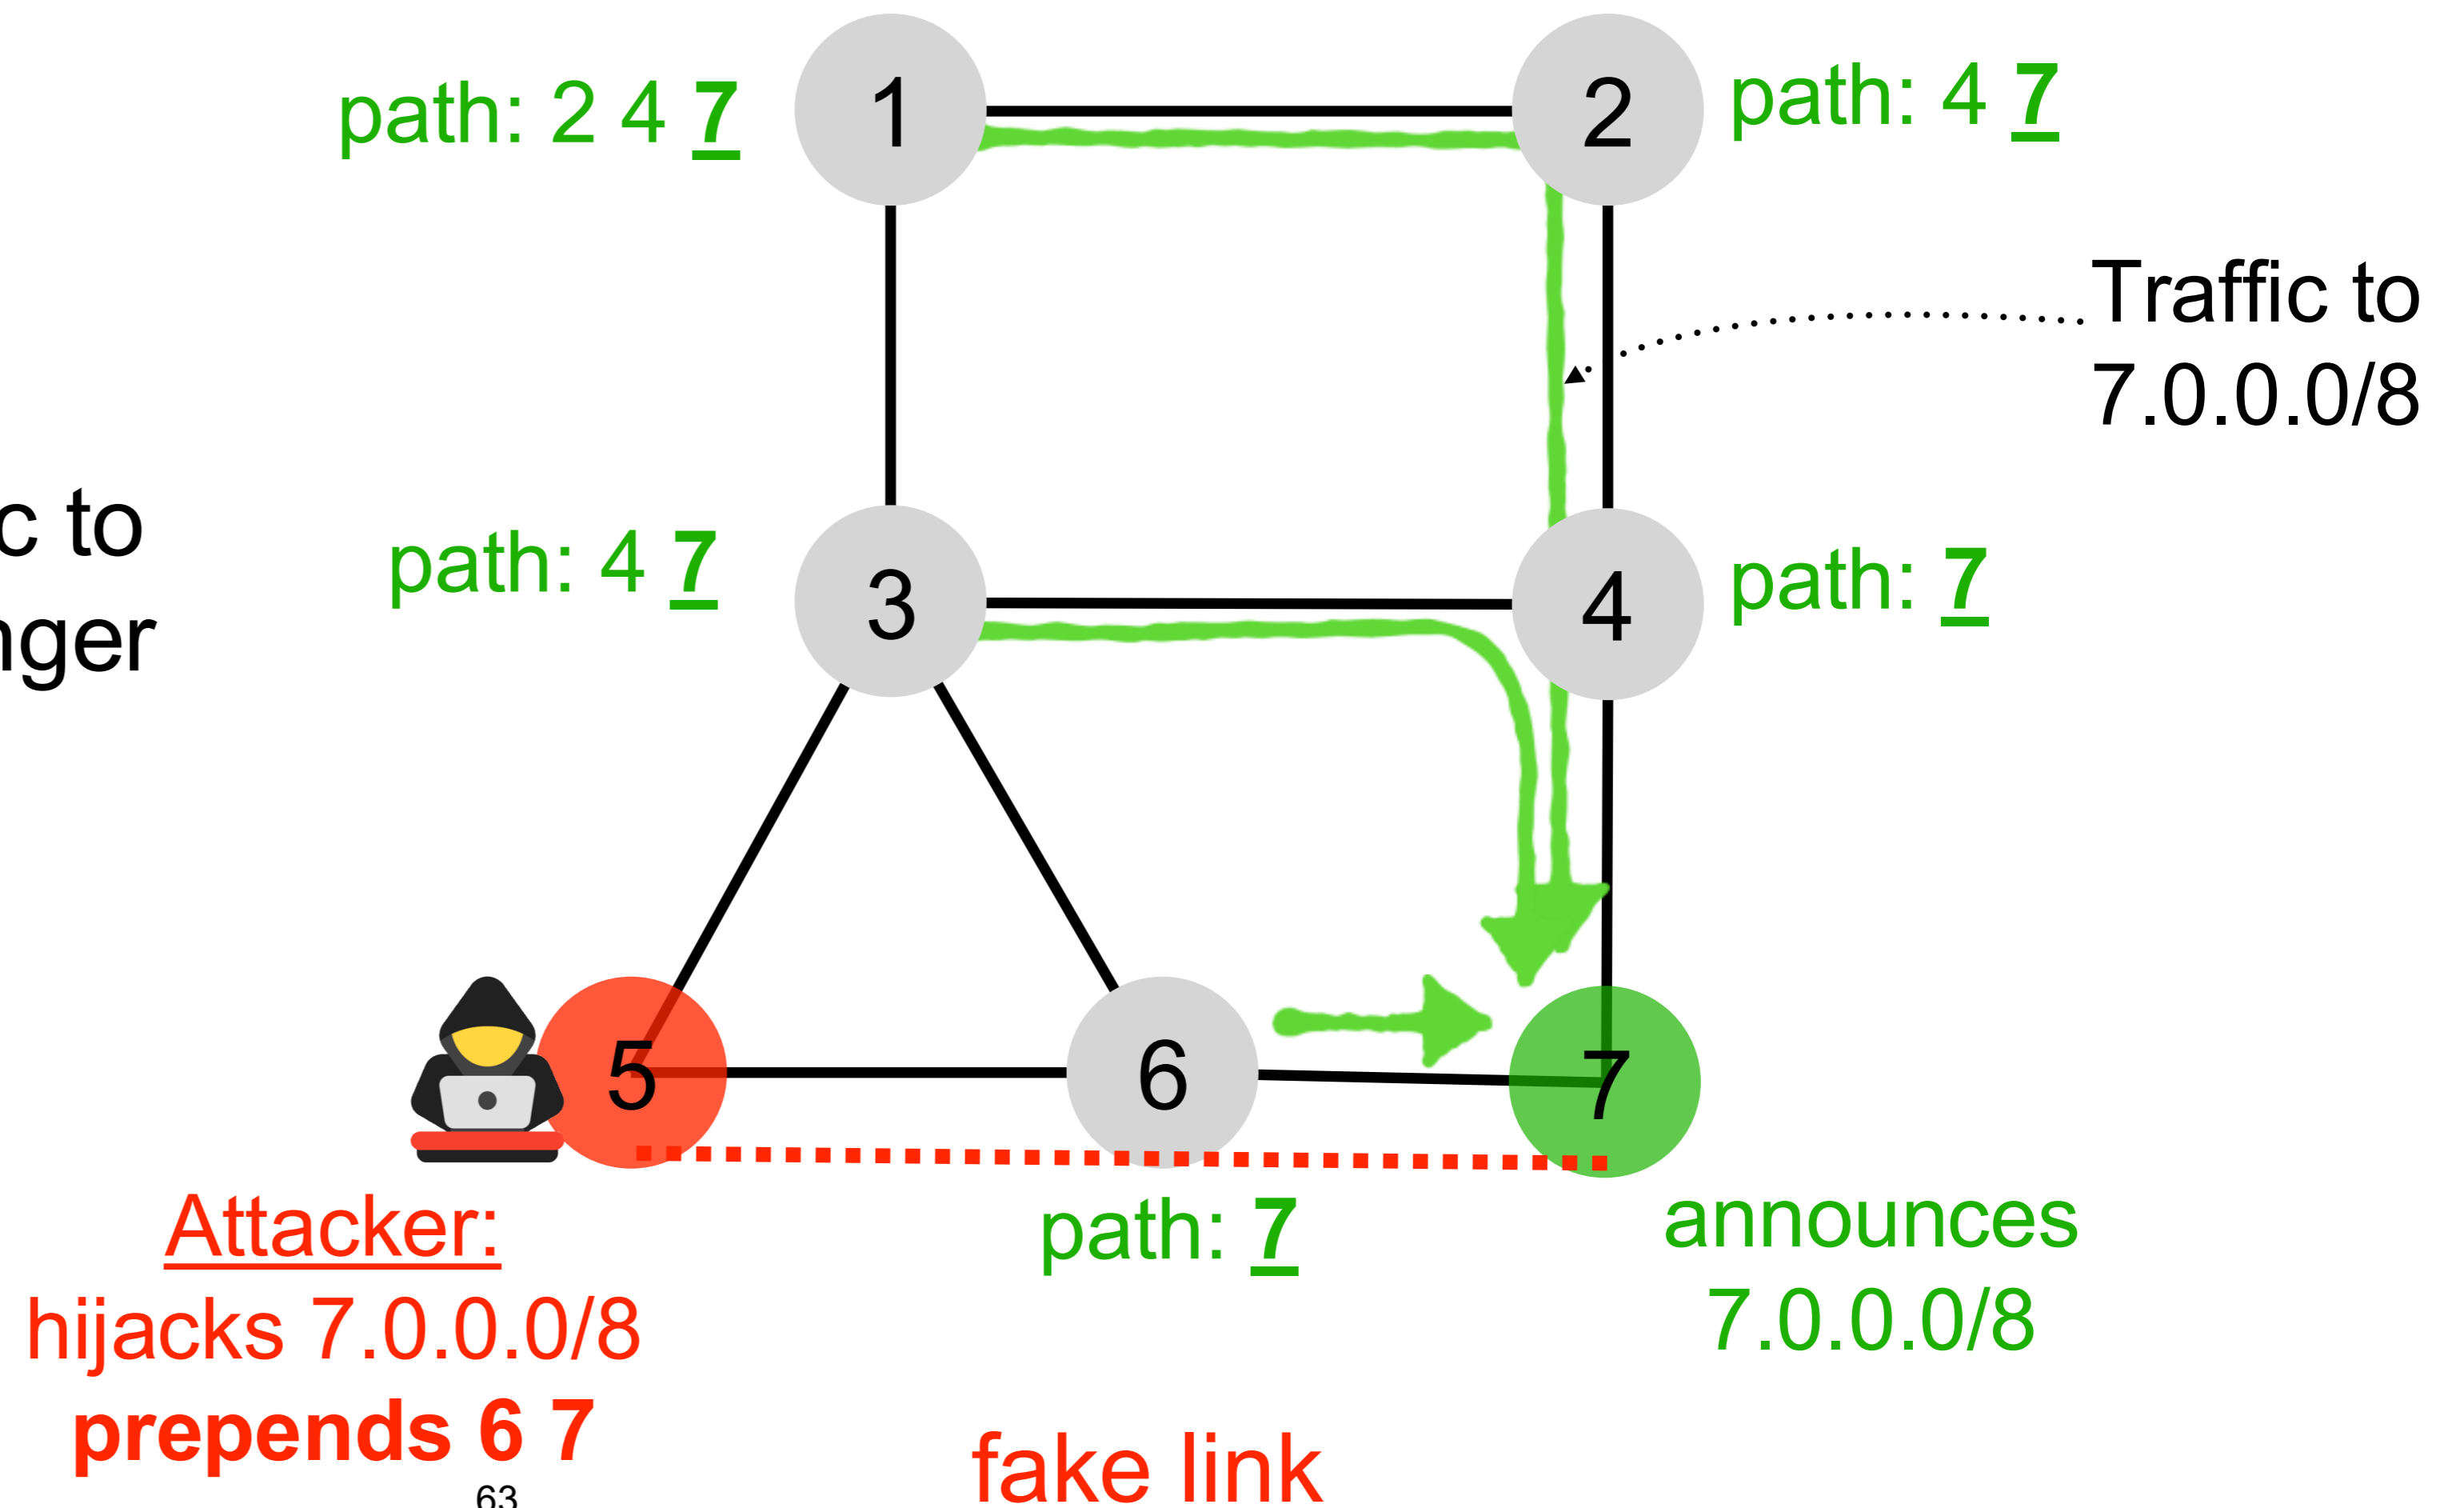

Upon the attack:  
AS5 (*attacker*) and AS7 (*victim*) appear directly connected

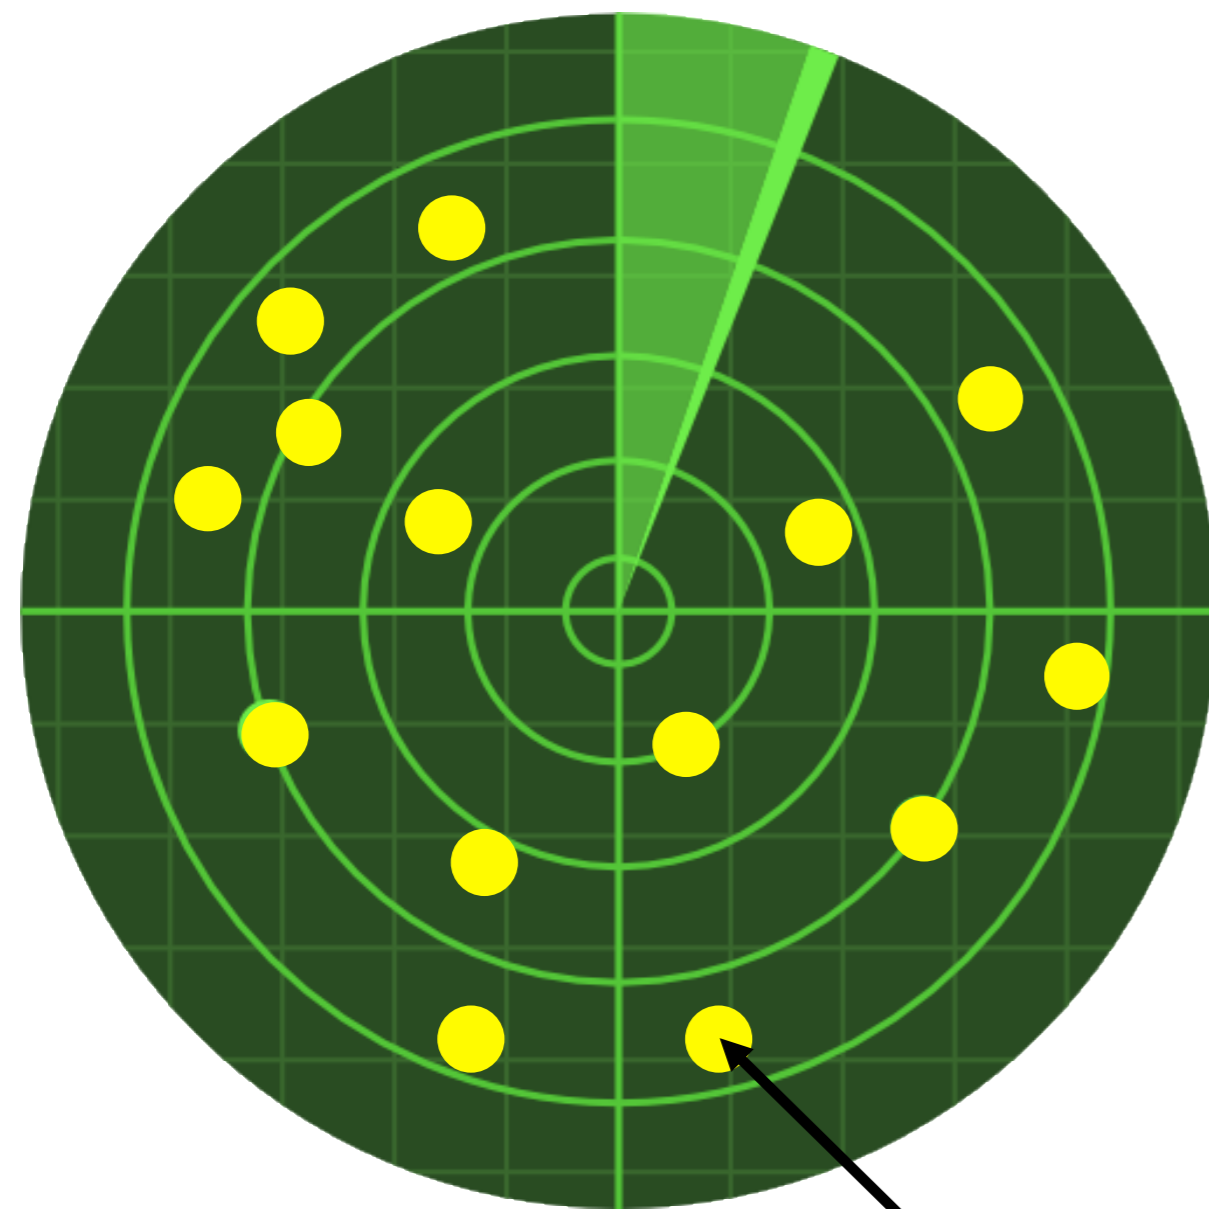

An attacker **cannot escape** from creating a fake AS link without hampering the effectiveness of its attack

There is no new AS link if the attacker prepends **6 7**

But none of the ASes divert traffic to the attacker as the AS path is longer

**Problem:** There are many new AS links every day  
but **no simple property** that tells whether they are real or fake

New AS link

We find 166 new AS links every day (median)  
and the vast majority are likely legitimate

Using the BGP data from 200 RIS and RouteViews  
peers and collected during ten months in 2022

**Problem:** There are many new AS links every day  
but **no simple property** that tells whether they are real or fake

# Outline

**DFOH's main challenge**

**ABSTRACT** Routing hijack attacks have plagued the Internet for decades. After many failed mitigation attempts, recent Internet-wide BGP monitoring infrastructures relying on distributed route collection systems, called route collectors, give us hope that future monitor systems can quickly detect and ultimately mitigate hijacks. In this paper, we investigate the effectiveness of public route collectors with respect to future attackers deliberately engineering longer hijacks to avoid being recorded by route collectors. Our extensive simulations (and attacks we devise) show that monitor-based systems may be unable to observe many carefully crafted hijacks diverting traffic from thousands of ASes. Hijackers could predict whether their attacks would propagate to some BGP feeders (i.e., monitors) of public route collectors. Then, manipulate BGP route propagation so that the attack never reaches those monitors. This observation remains true when considering plausible future Internet topologies, with more IXP links and up to 4 times more monitors peering with route collectors. We then evaluate the feasibility of performing hijacks not observed by route collectors in the real-world. We experiment with two classifiers to predict the monitors that are dangerous to report the attack to route collectors, one based on monitor proximities (i.e., shortest path lengths) and another based on Gao-Rexford routing policies. We show that a proximity-based classifier could be sufficient for the hijacker to identify all dangerous monitors for hijacks announced to peer-to-peer neighbors. For hijacks announced to transit networks, a Gao-Rexford classifier reduces wrong inferences by  $\geq 91\%$  without introducing new misclassifications for existing dangerous monitors.

**INDEX TERMS** BGP, BGP hijacking, stealthy IP prefix hijacking, inter-domain routing, routing policies, route collectors, forged AS path, BGP monitoring, BGPStream.

### I. INTRODUCTION

Routing hijacks keep affecting industry (including Google, Amazon, Apple, Microsoft) [1], [2], financial platforms (e.g., the Bitcoin network) [3], security authorities [4], Internet services [5], governments [6], and citizens [7]. 775 (830) suspicious BGP hijack (route leak) incidents have been documented in 2021 [8], and more than 2200 (1200) suspicious BGP hijack (route leak) incidents have been documented in

2020, a 30% hijack increase from 2019 [9].<sup>1</sup> This is mainly because BGP allows attackers to inject arbitrary information in the Internet routing system. By falsely claiming ownership of IP prefixes, malicious networks can divert, eavesdrop, store, and possibly modify traffic in so-called *interception attacks*.<sup>2</sup>

<sup>1</sup>While the references distinguish between route leaks and BGP hijacks, we consider them analogous terms, both classified under the category of Type-N attacks, which we will introduce formally in Section III-A.

<sup>2</sup>BGP hijacks can be used to drop traffic as well. We focus on interception attacks as they are harder to detect for the victim.

The associate editor coordinating the review of this manuscript and approving it for publication was Salekul Islam .

Because of the inherent path hiding nature of BGP, each VP only has a **partial view** over Internet routing

RIPE RIS  
RouteViews

From VP1 drop p1 p2

Now I can see that p1 p2 share the same BGP attributes

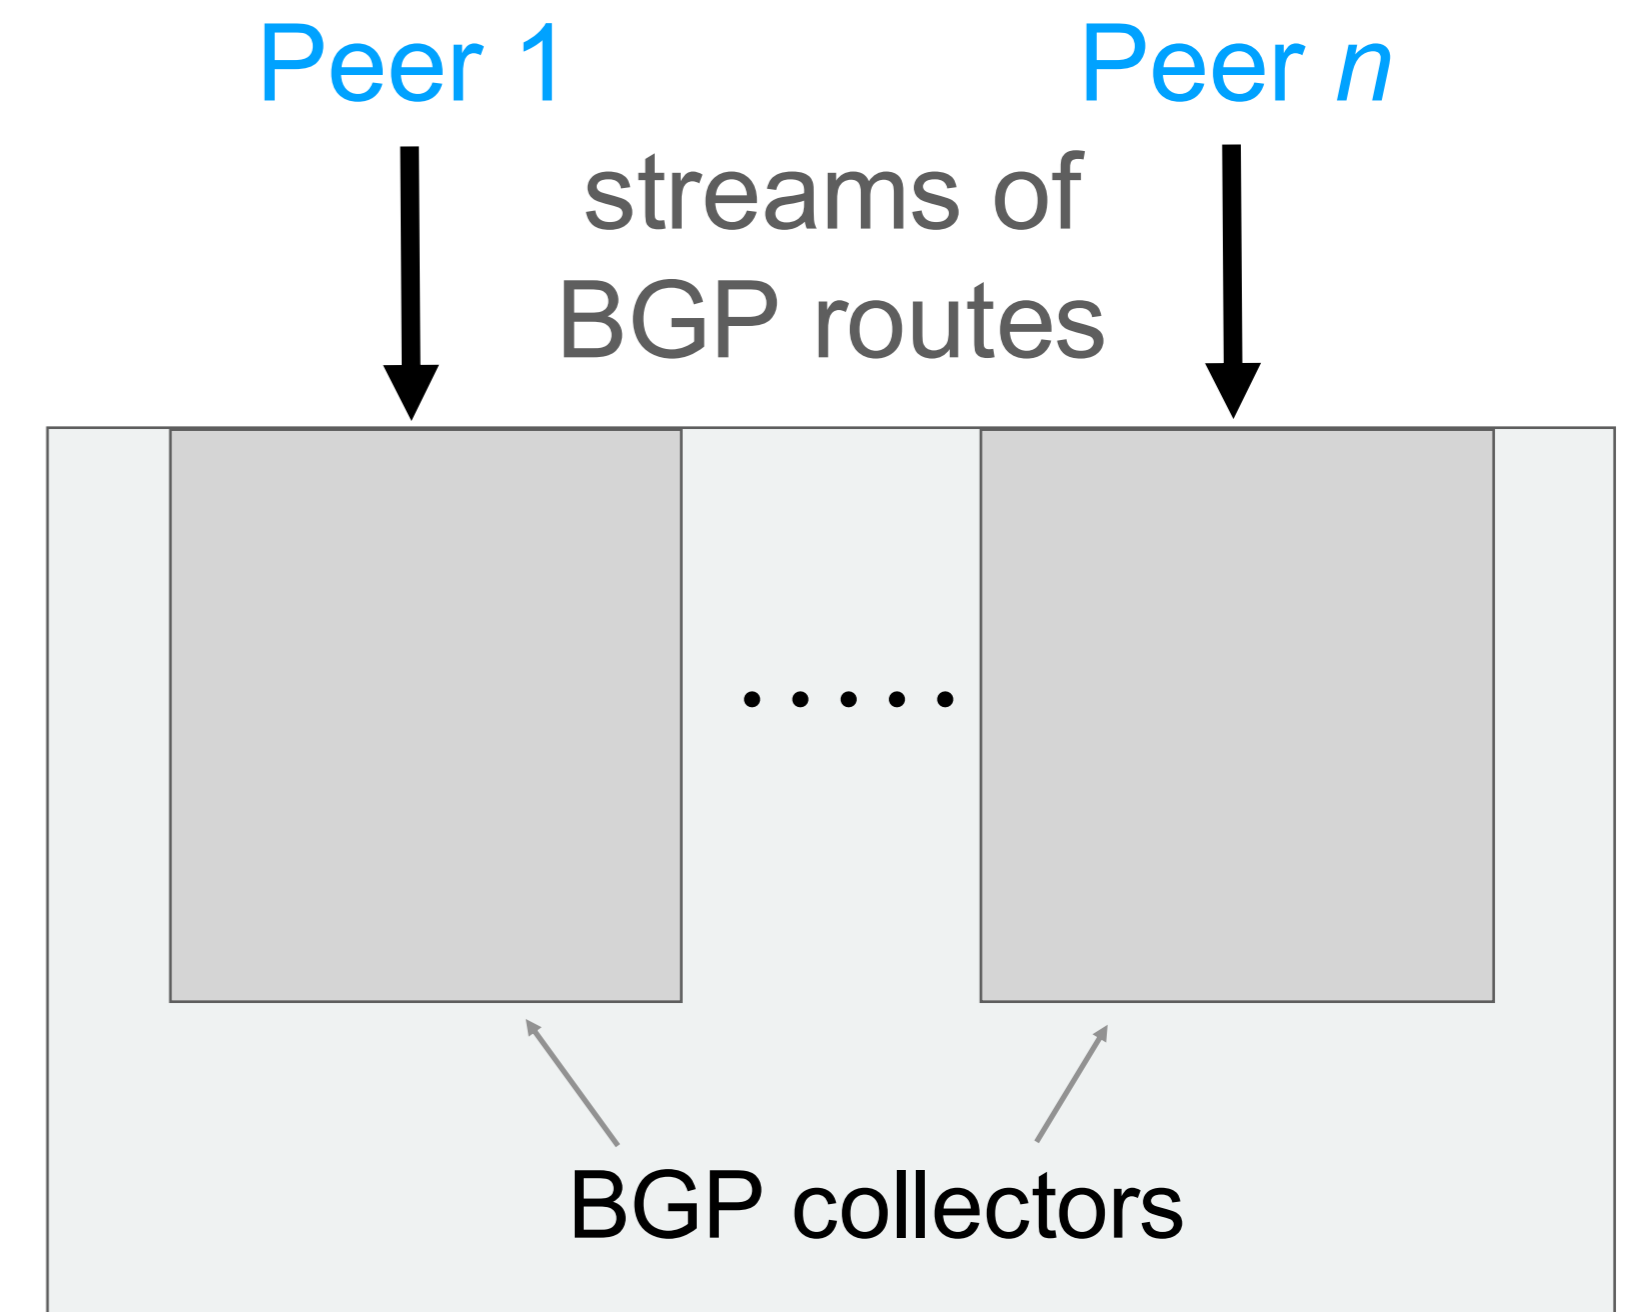

# Outline

1. We observe that BGP routes are often redundant
2. Redundant BGP routes enable an overshoot-and-discard collection scheme
3. ***GILL***: a system that measures redundancy in BGP data and uses it to generate filters that retain only the useful routes

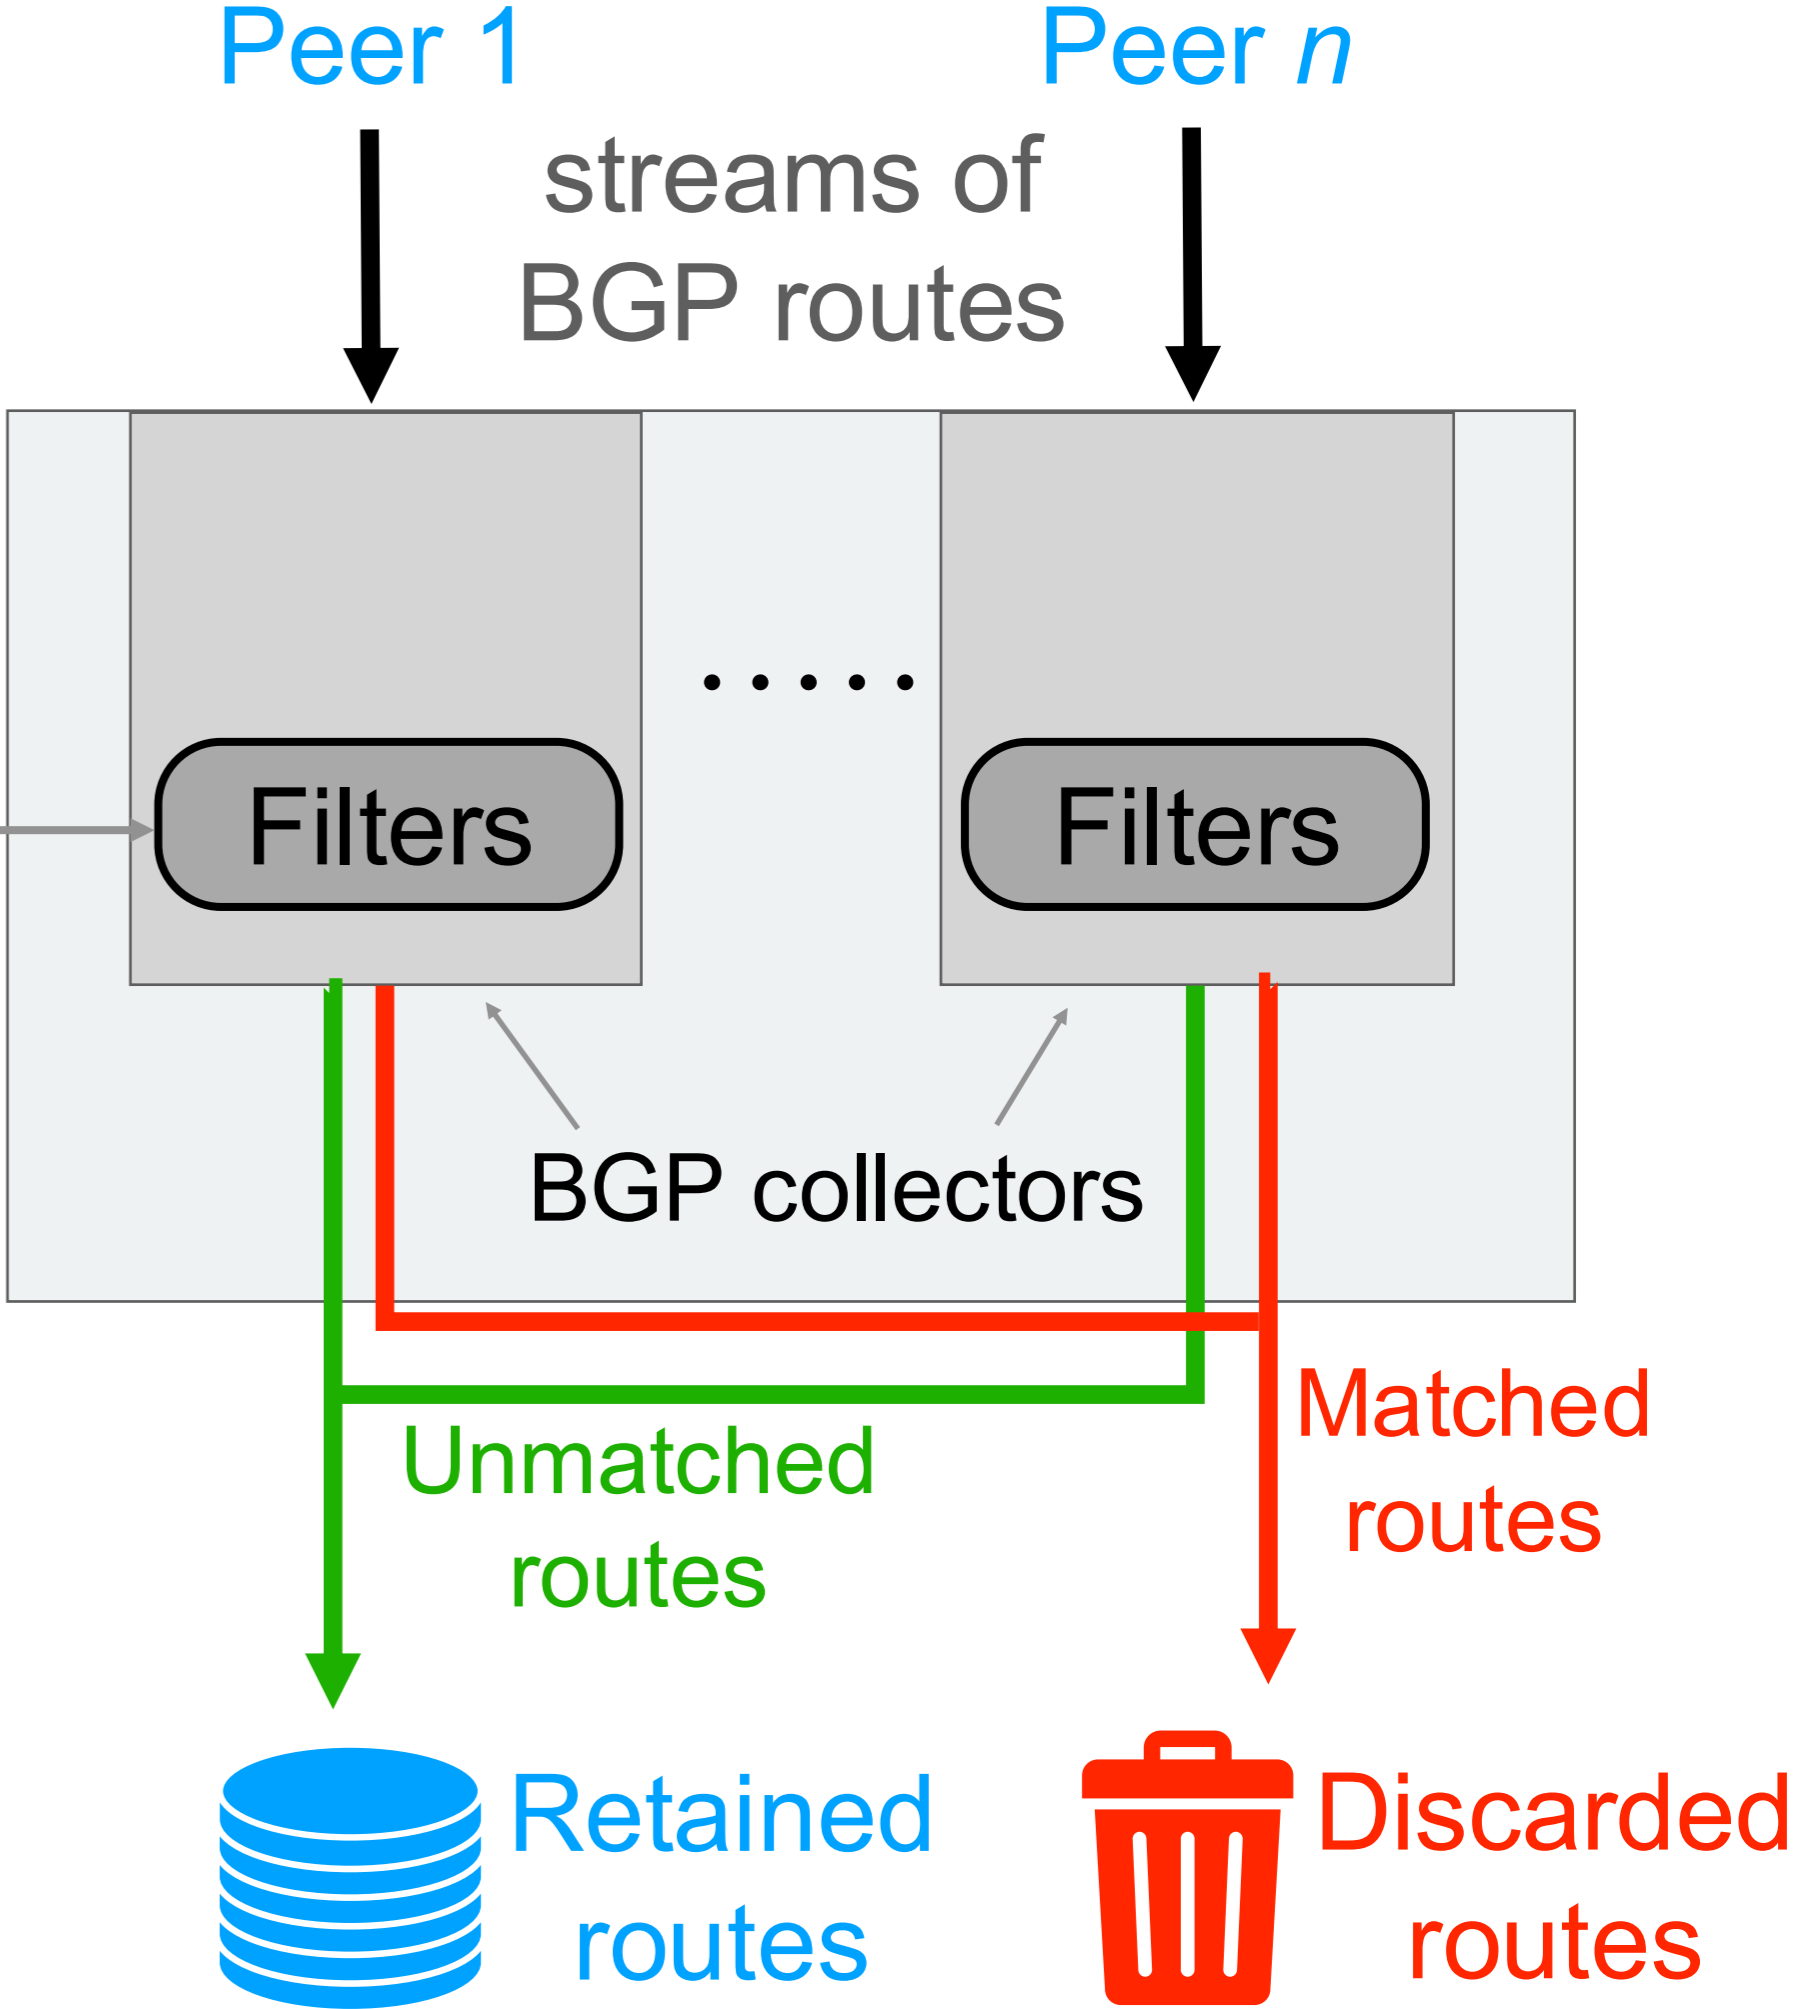

***GILL*** uses custom BGP collectors (one per peer)  
optimized to collect BGP route updates

***GILL*** supports  
10k+ BGP sessions  
(see paper)

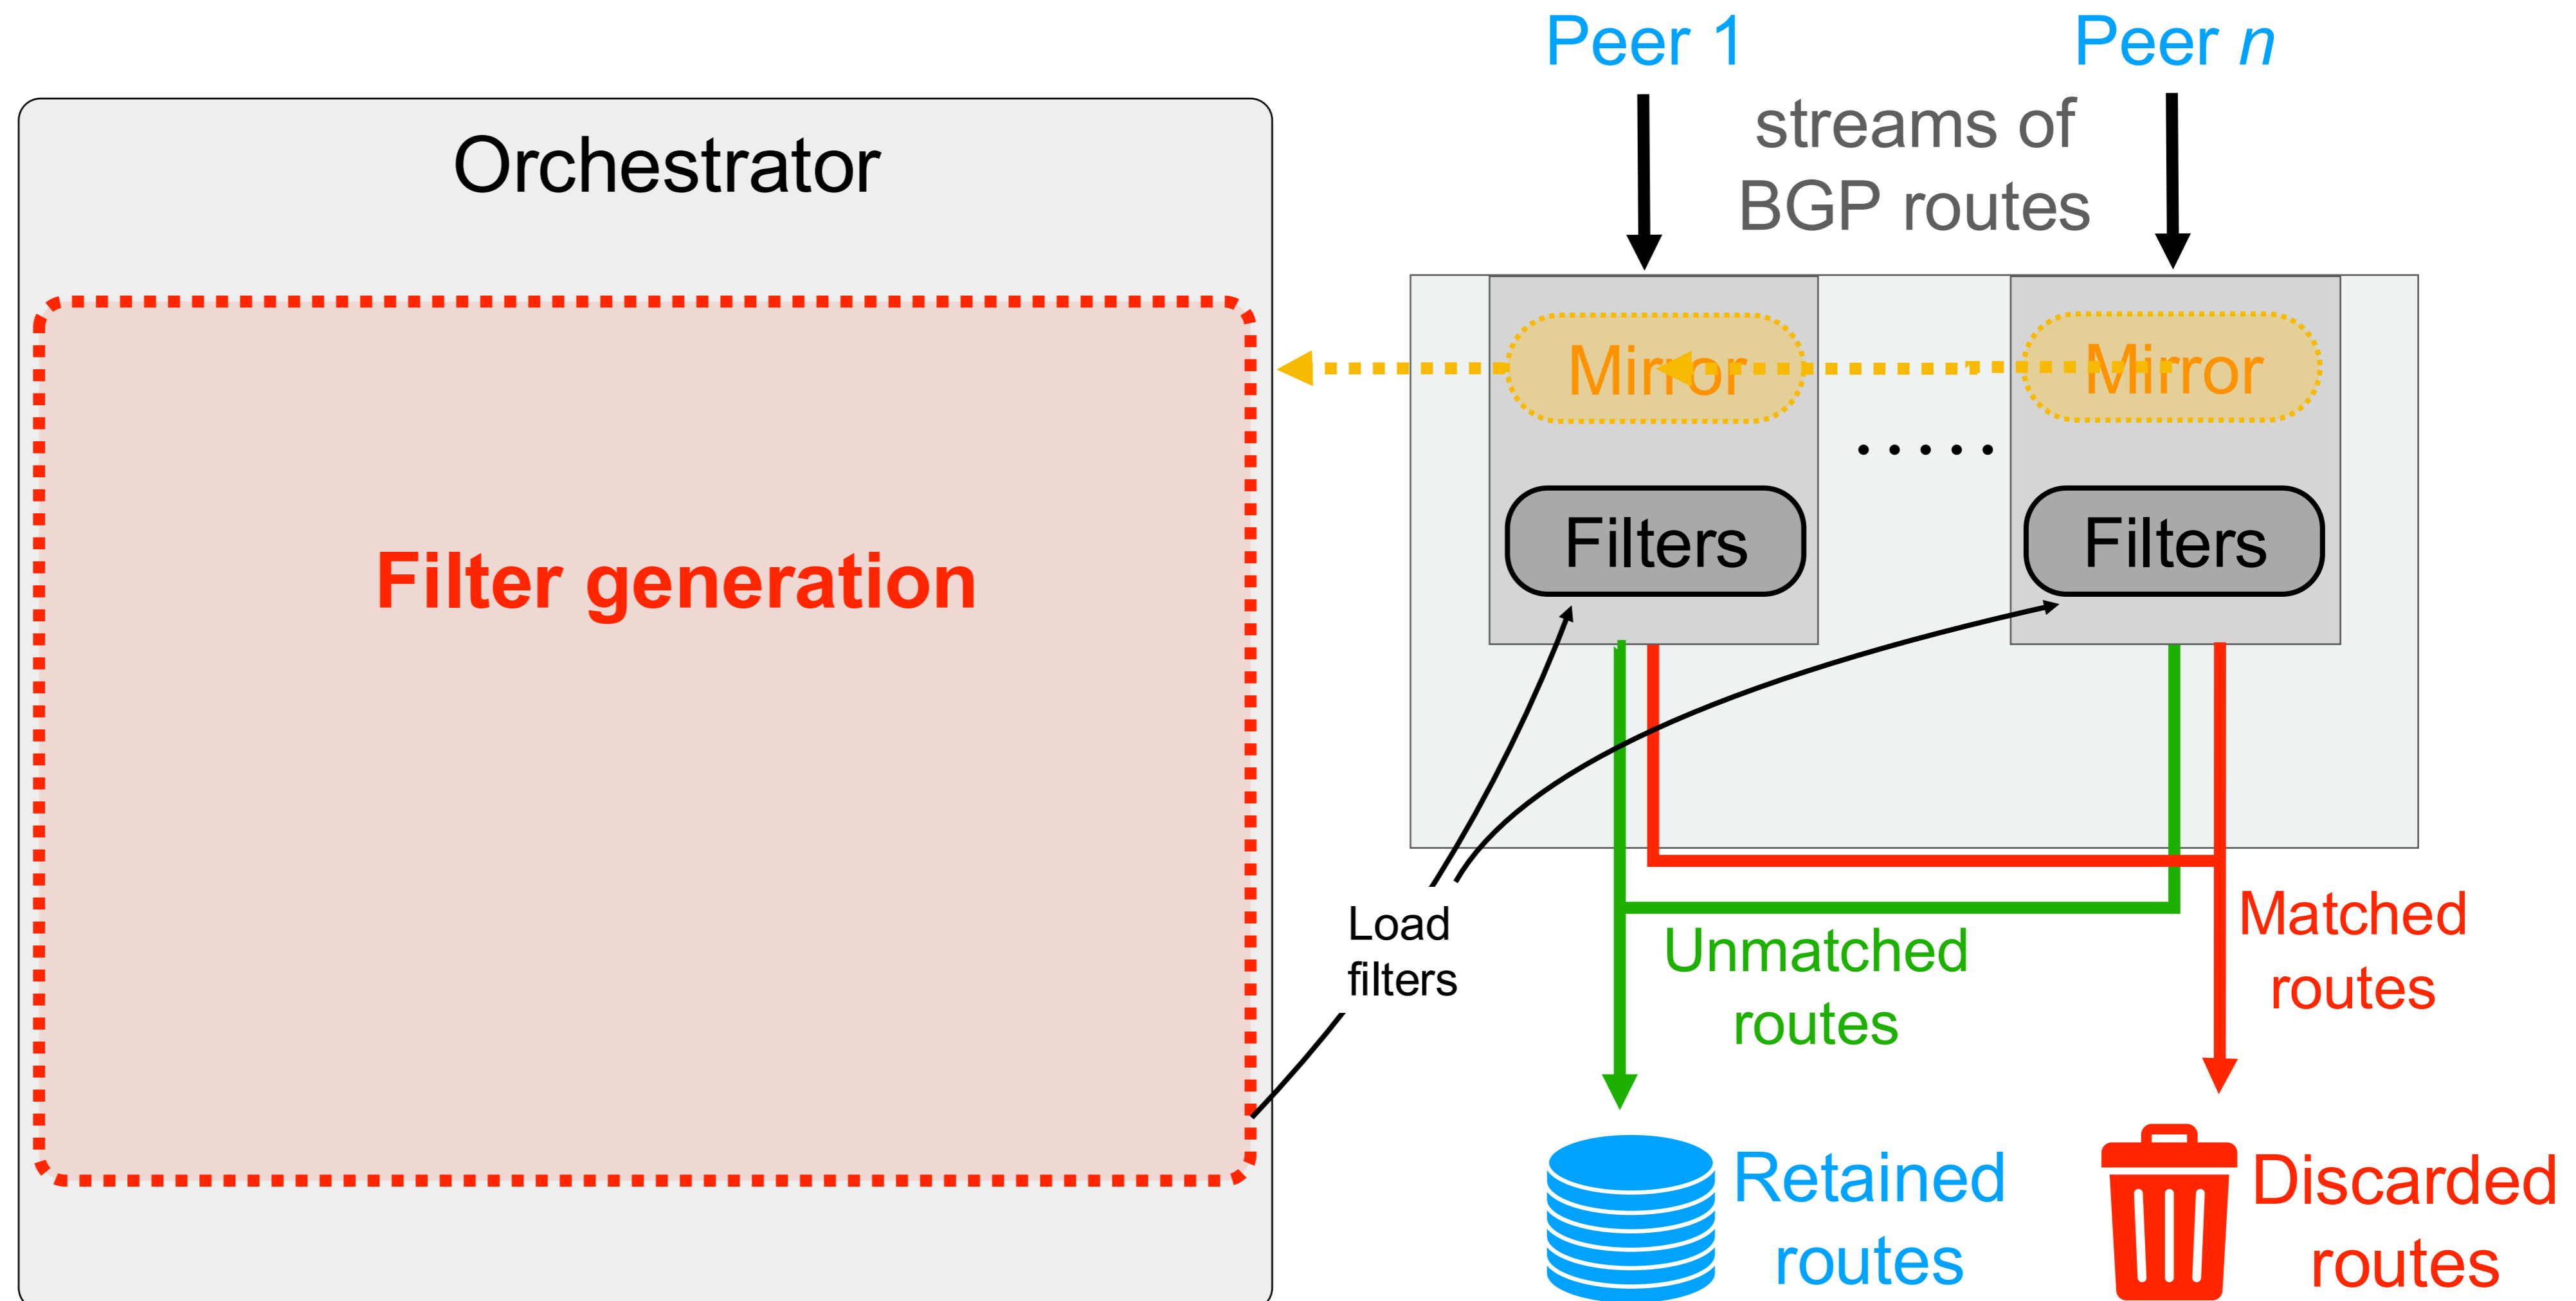

**GILL** discards the BGP routes that match filters and retains all the others

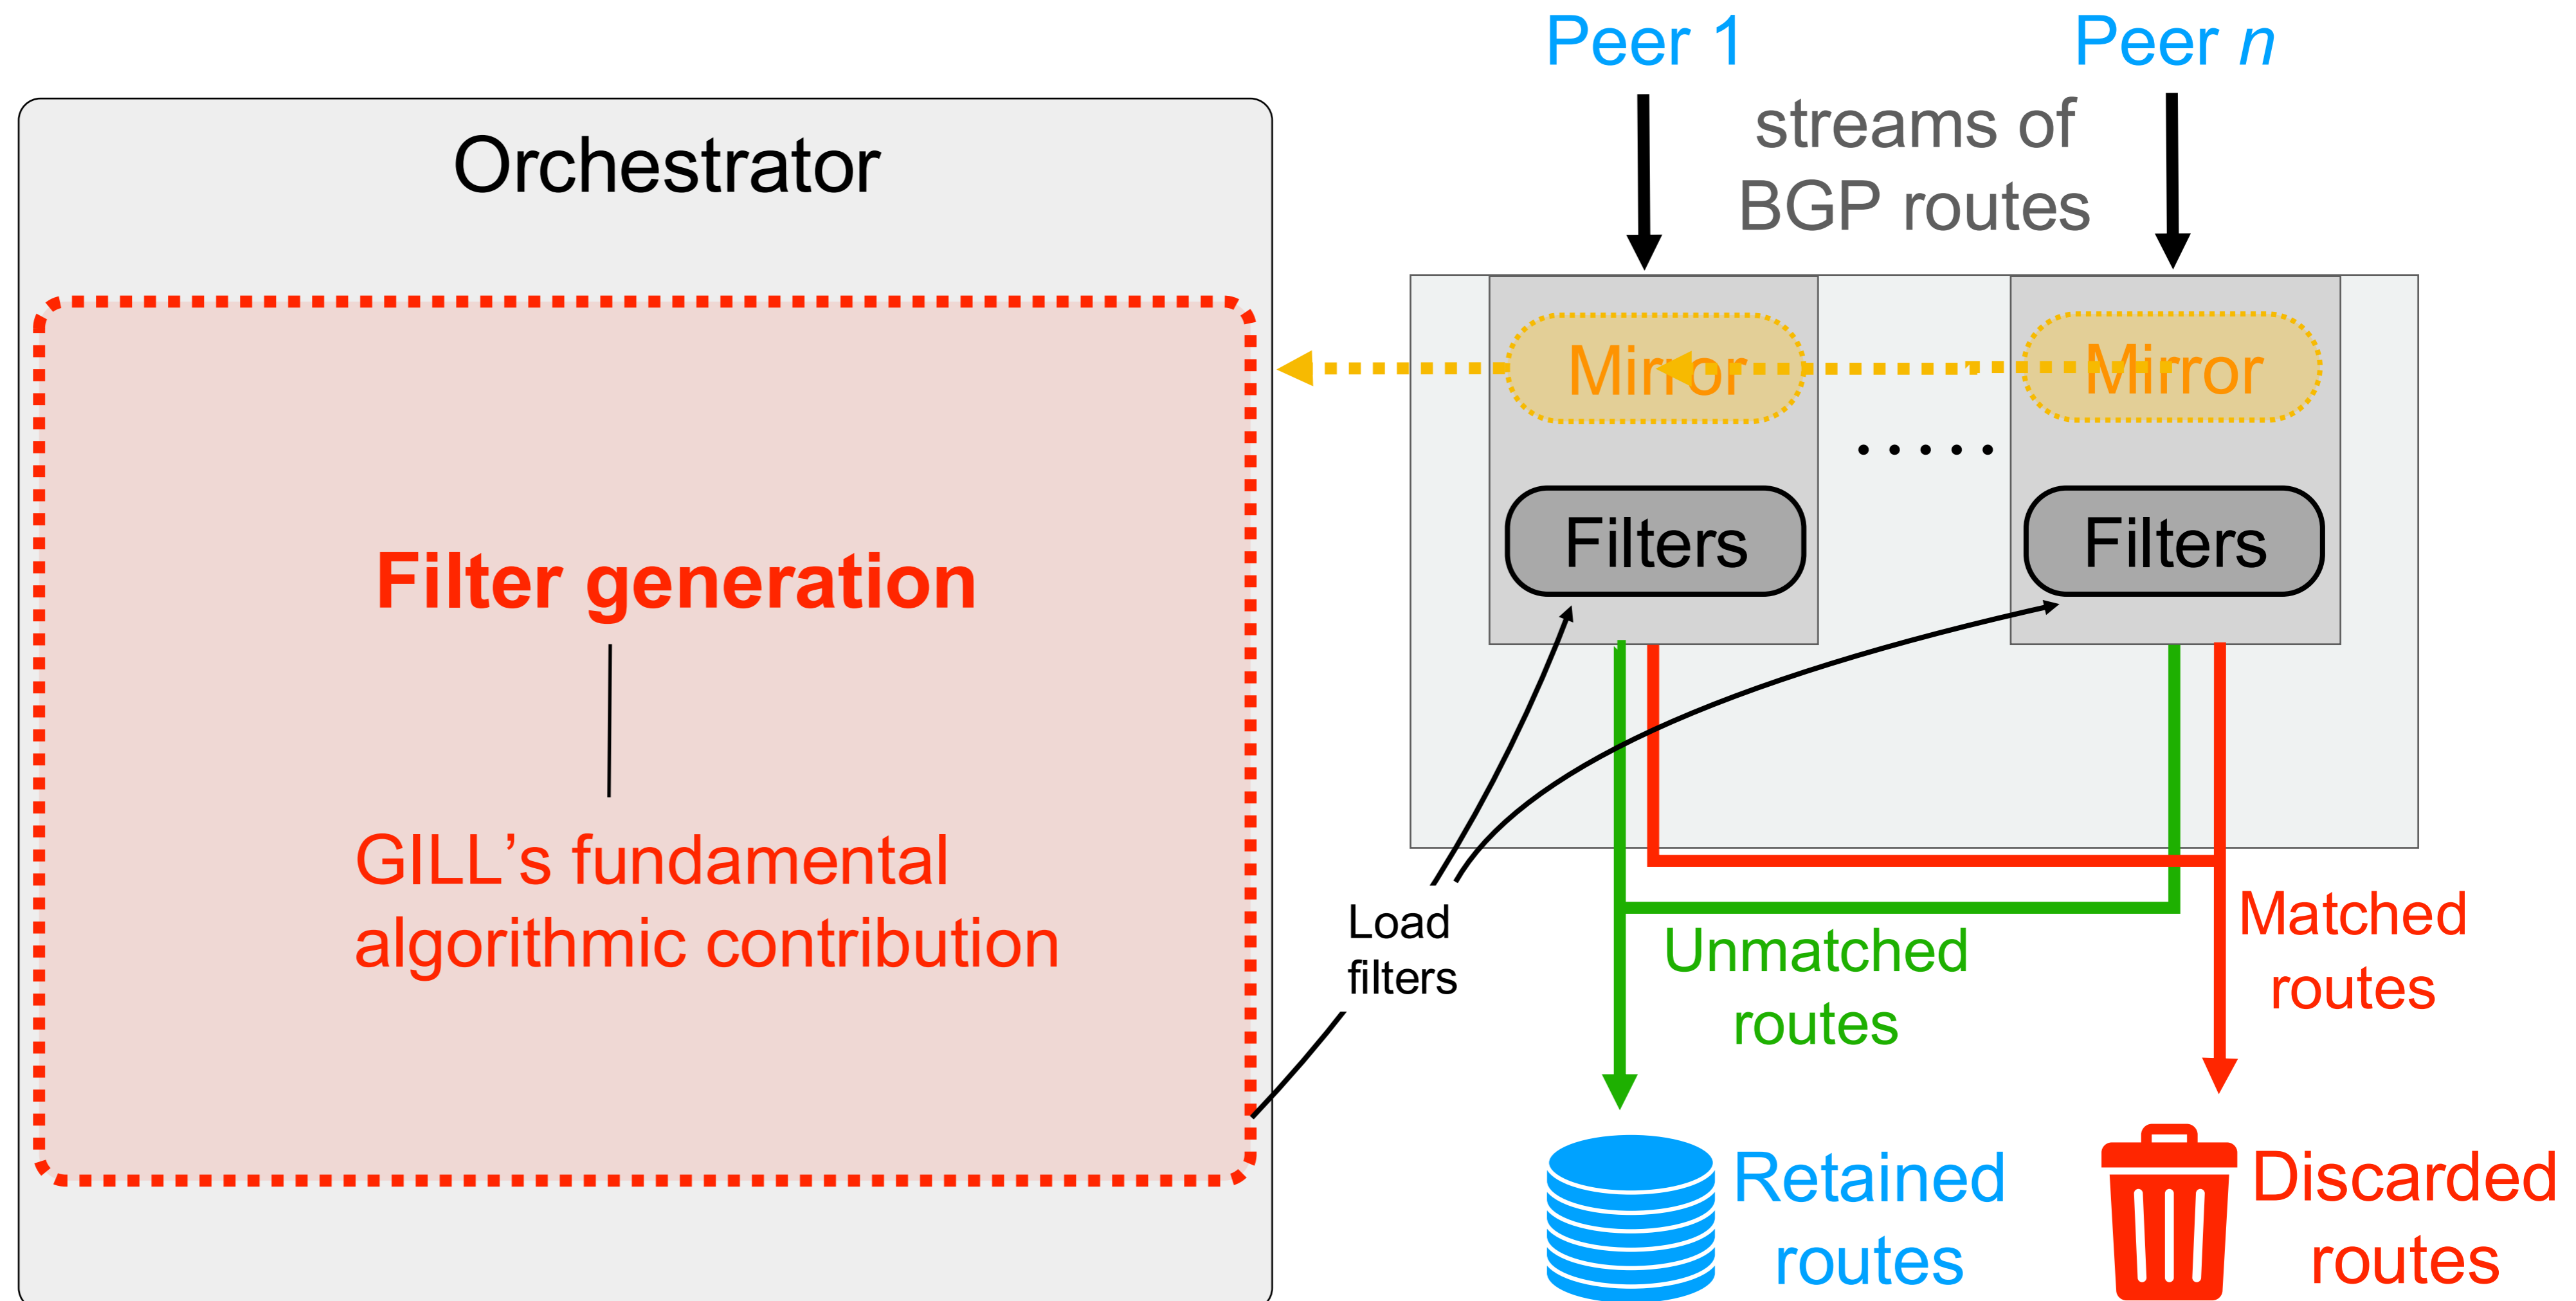

**GILL** installs the filters in the BGP collectors

# *GILL*'s filters generation is data driven

# *GILL*'s filters generation is data driven

# *GILL*'s filters generation has three steps

**Step#1:** Identifying redundancy in past BGP data

Challenging as there is no **consensus** on how to define redundancy in BGP data

# ***GILL***'s filters generation has three steps

**Step#1:** Identifying redundancy in past BGP data

Challenging as there is no **consensus** on how to define redundancy in BGP data

**Step#2:** Predict future redundancies in BGP data

Fortunately, redundancy in BGP data is **stable** over time (see paper)

# *GILL*'s filters generation has three steps

**Step#1:** Identifying redundancy in past BGP data

Challenging as there is no **consensus** on how to define redundancy in BGP data

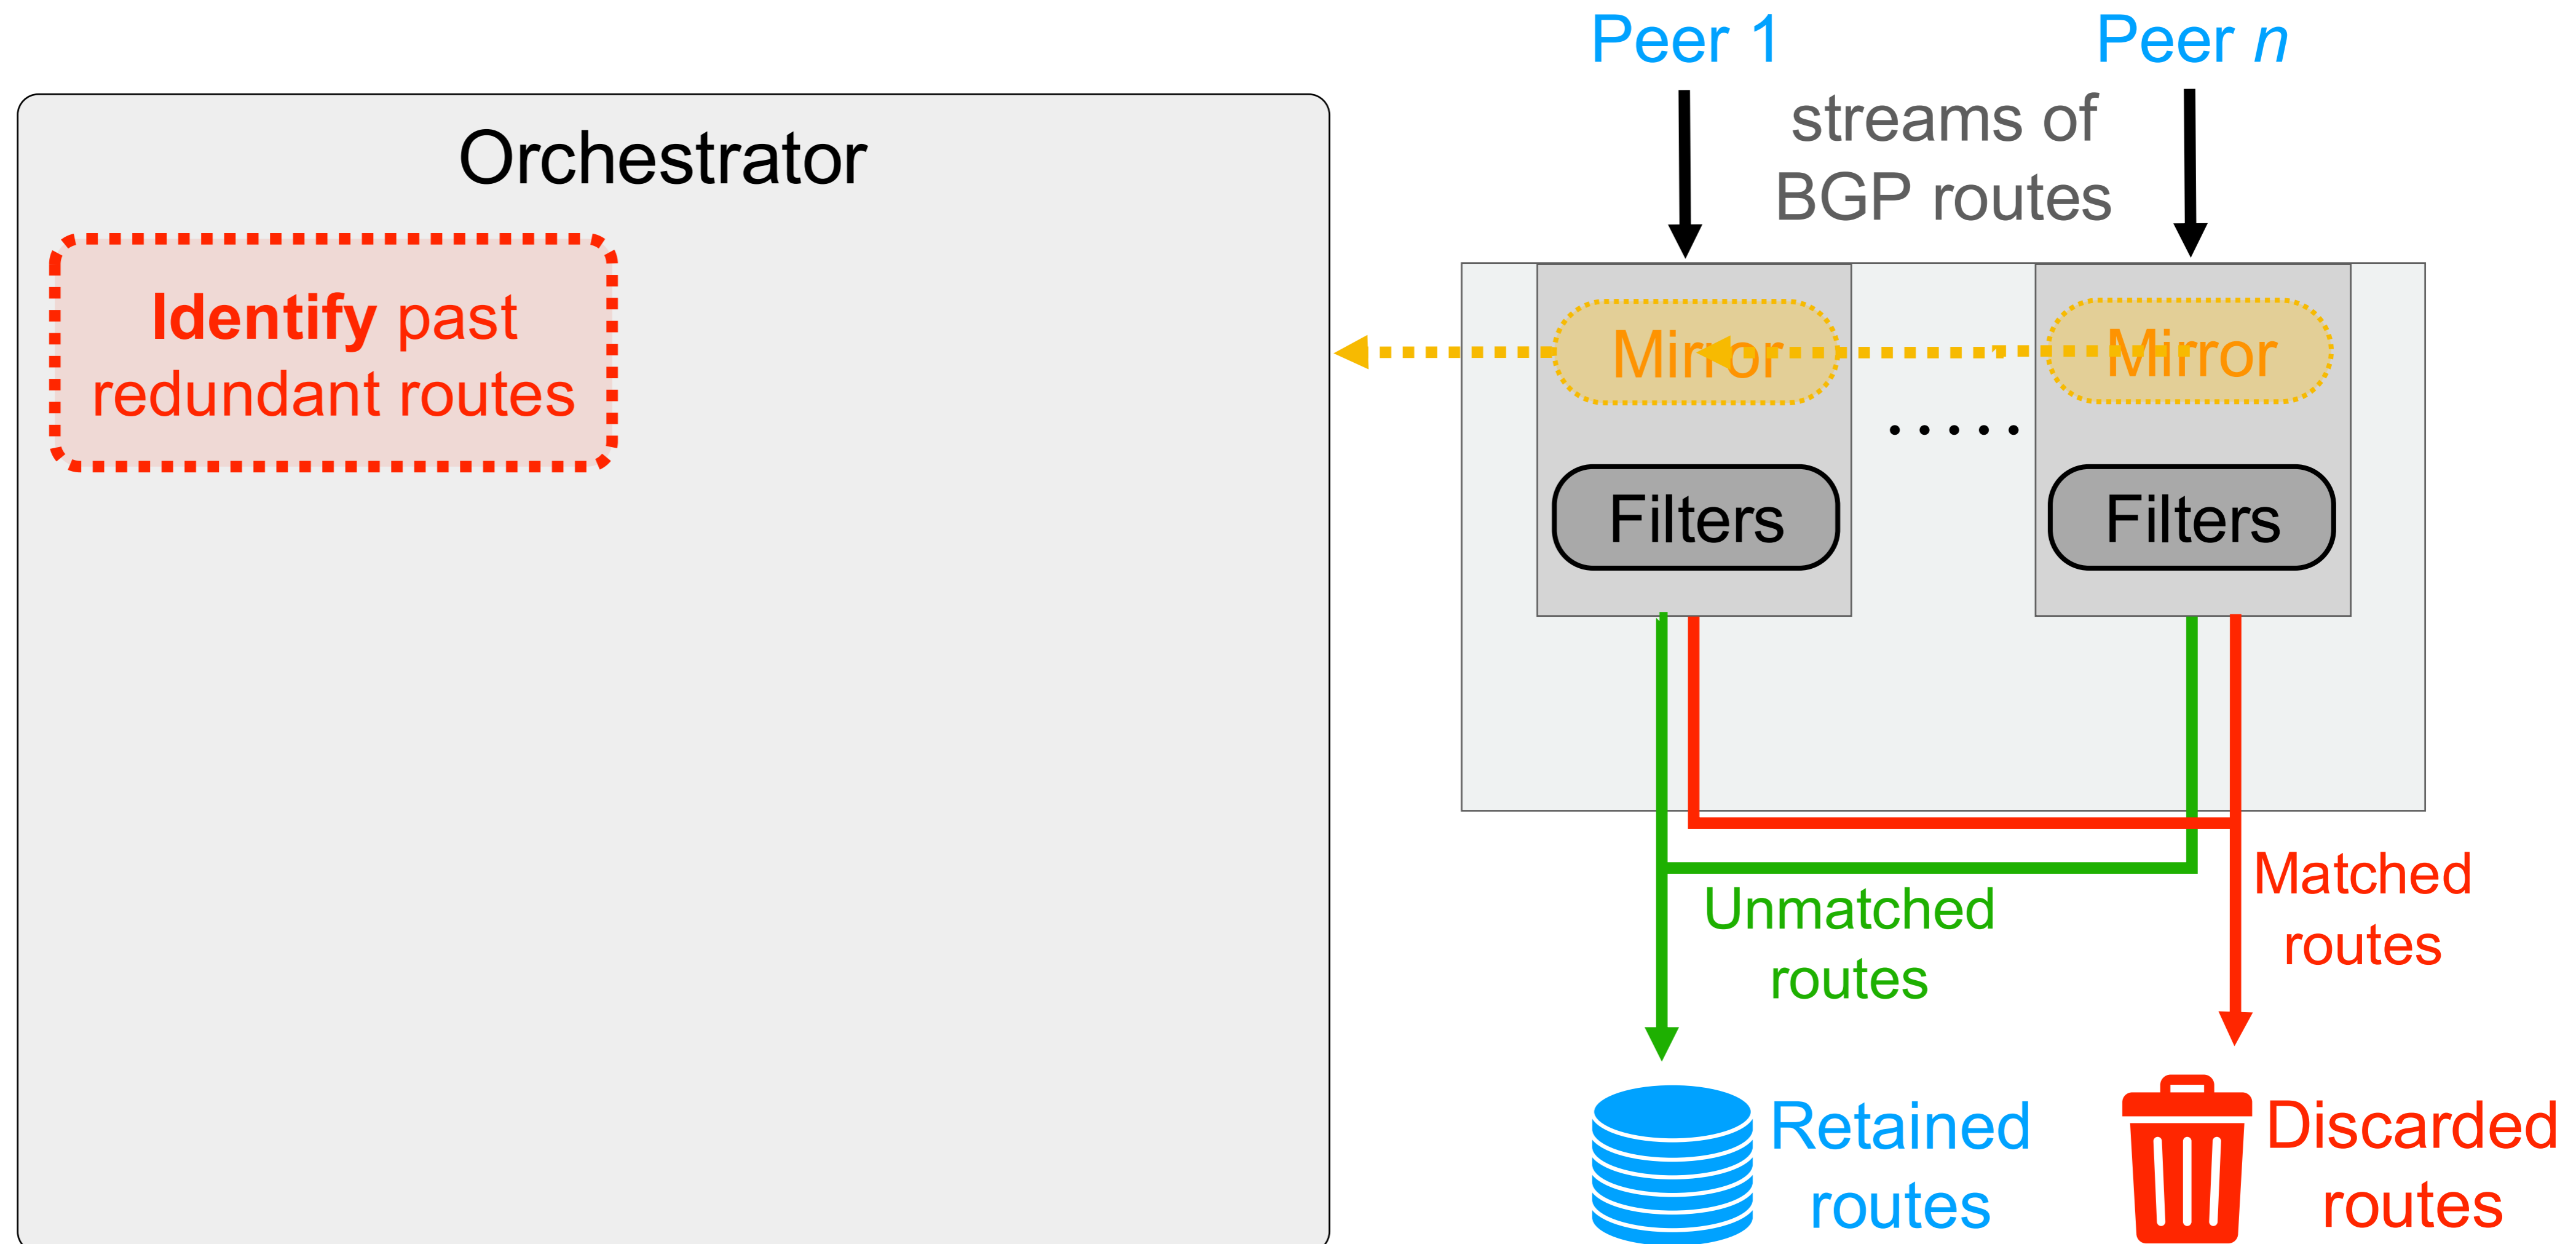

**Step#2:** Predict future redundancies in BGP data

Fortunately, redundancy in BGP data is **stable** over time (see paper)

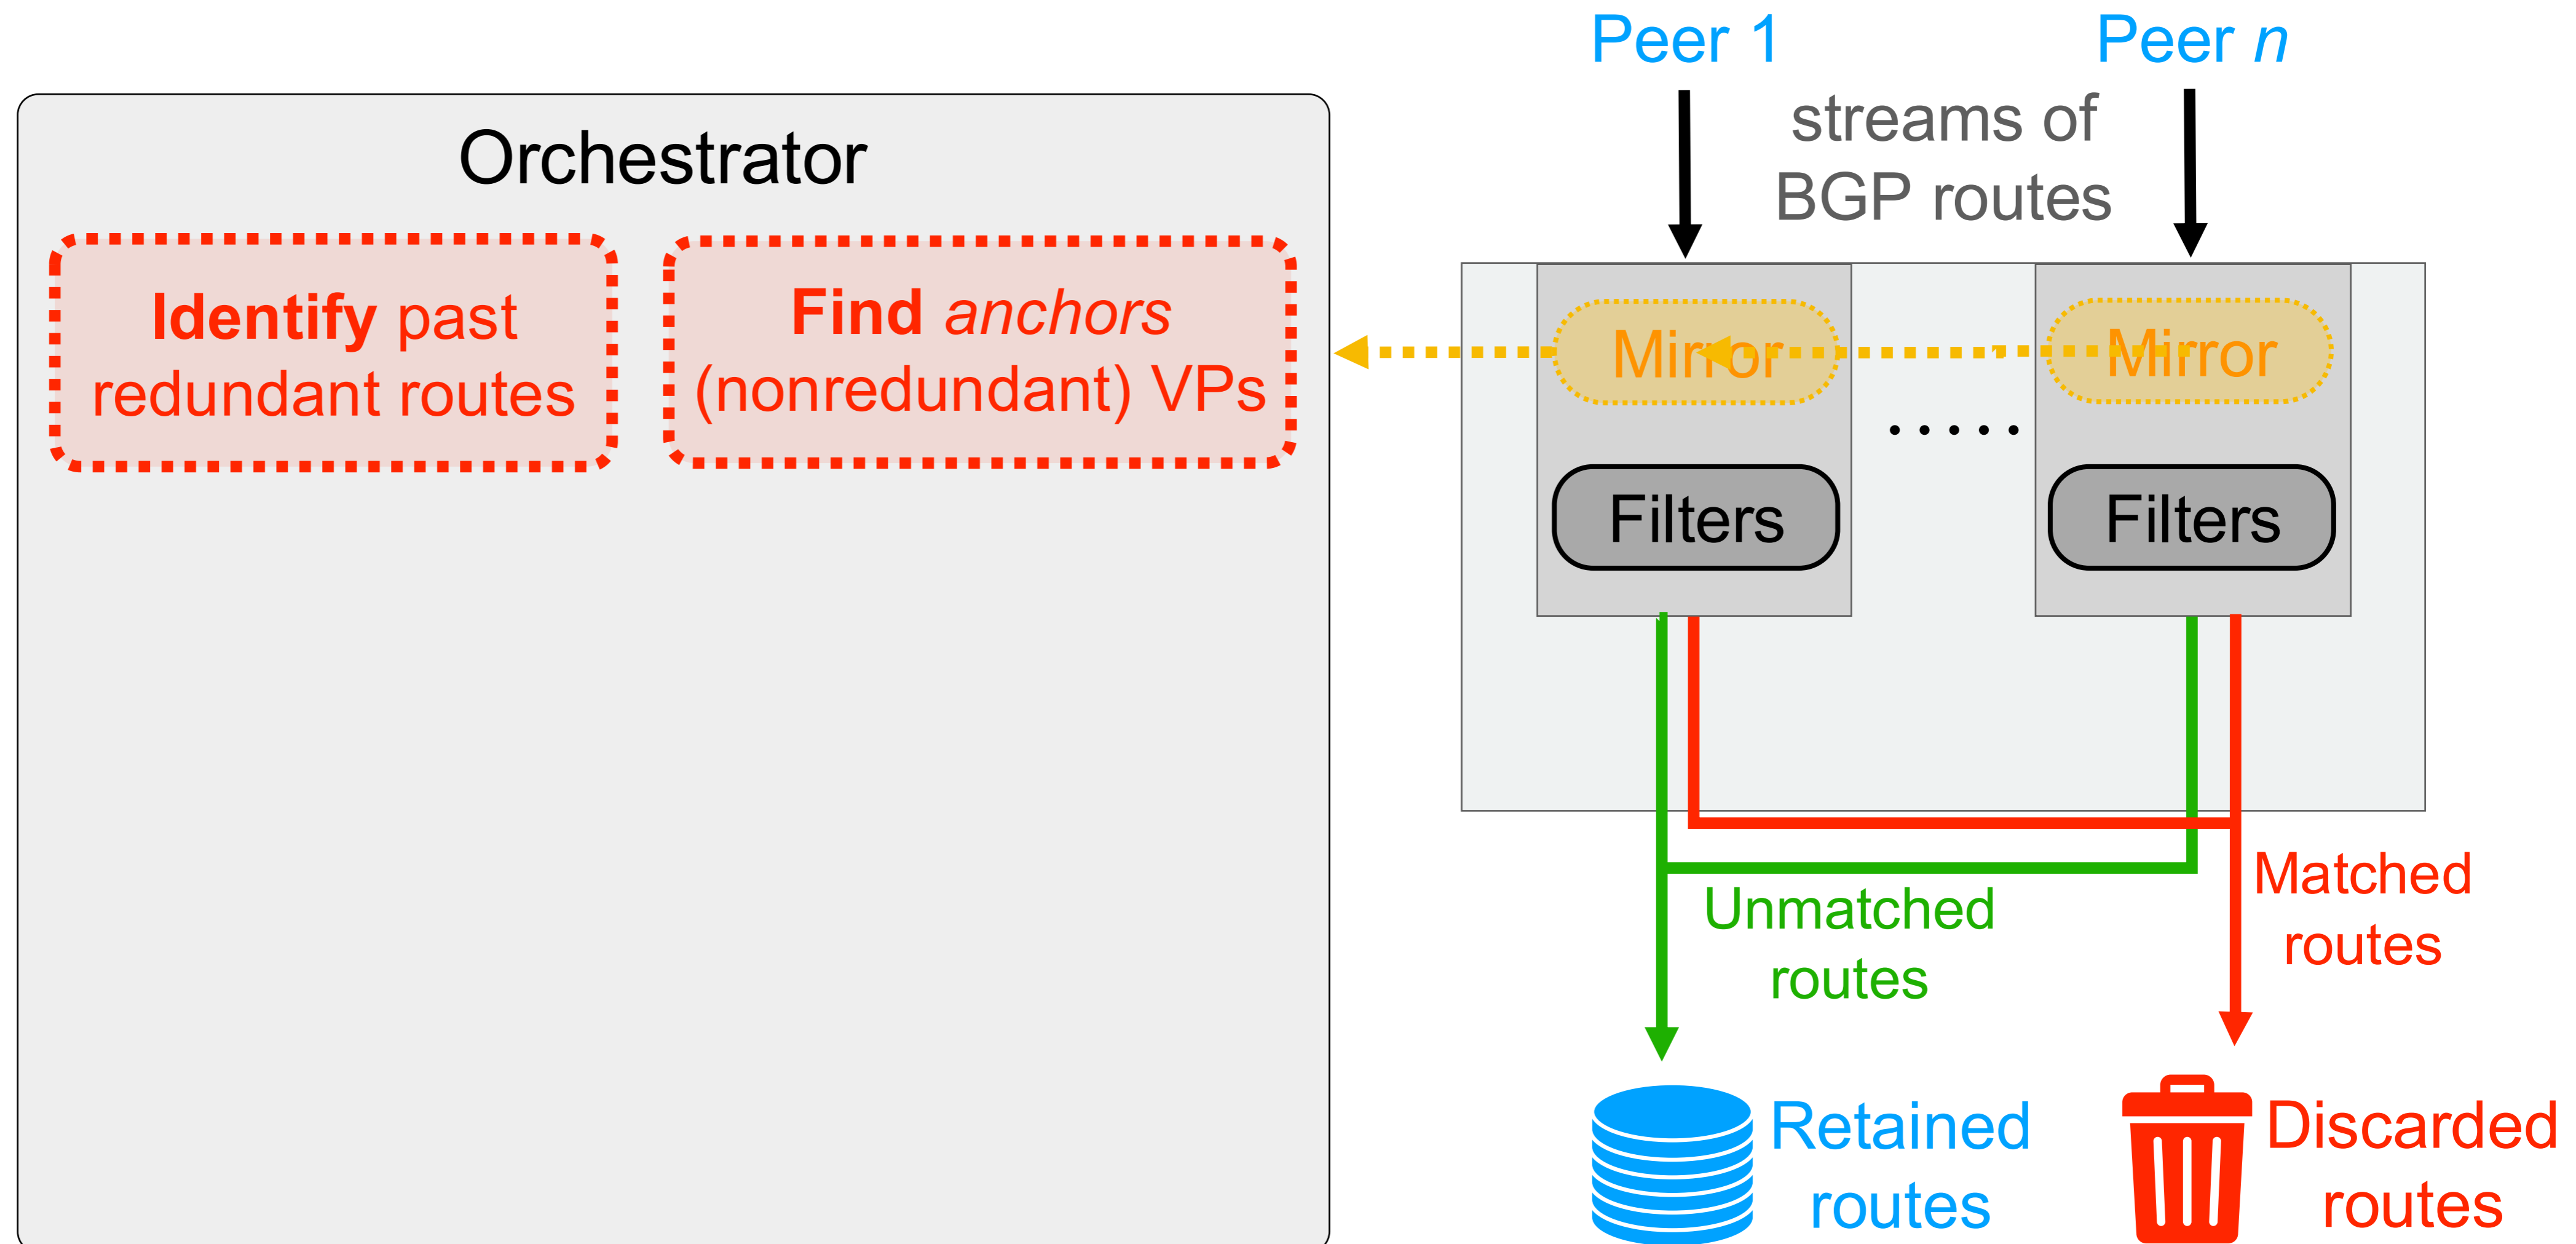

**Step#3:** Generate filters that retain useful bits of the BGP data

Challenging because we **cannot predict** what users will do with the data

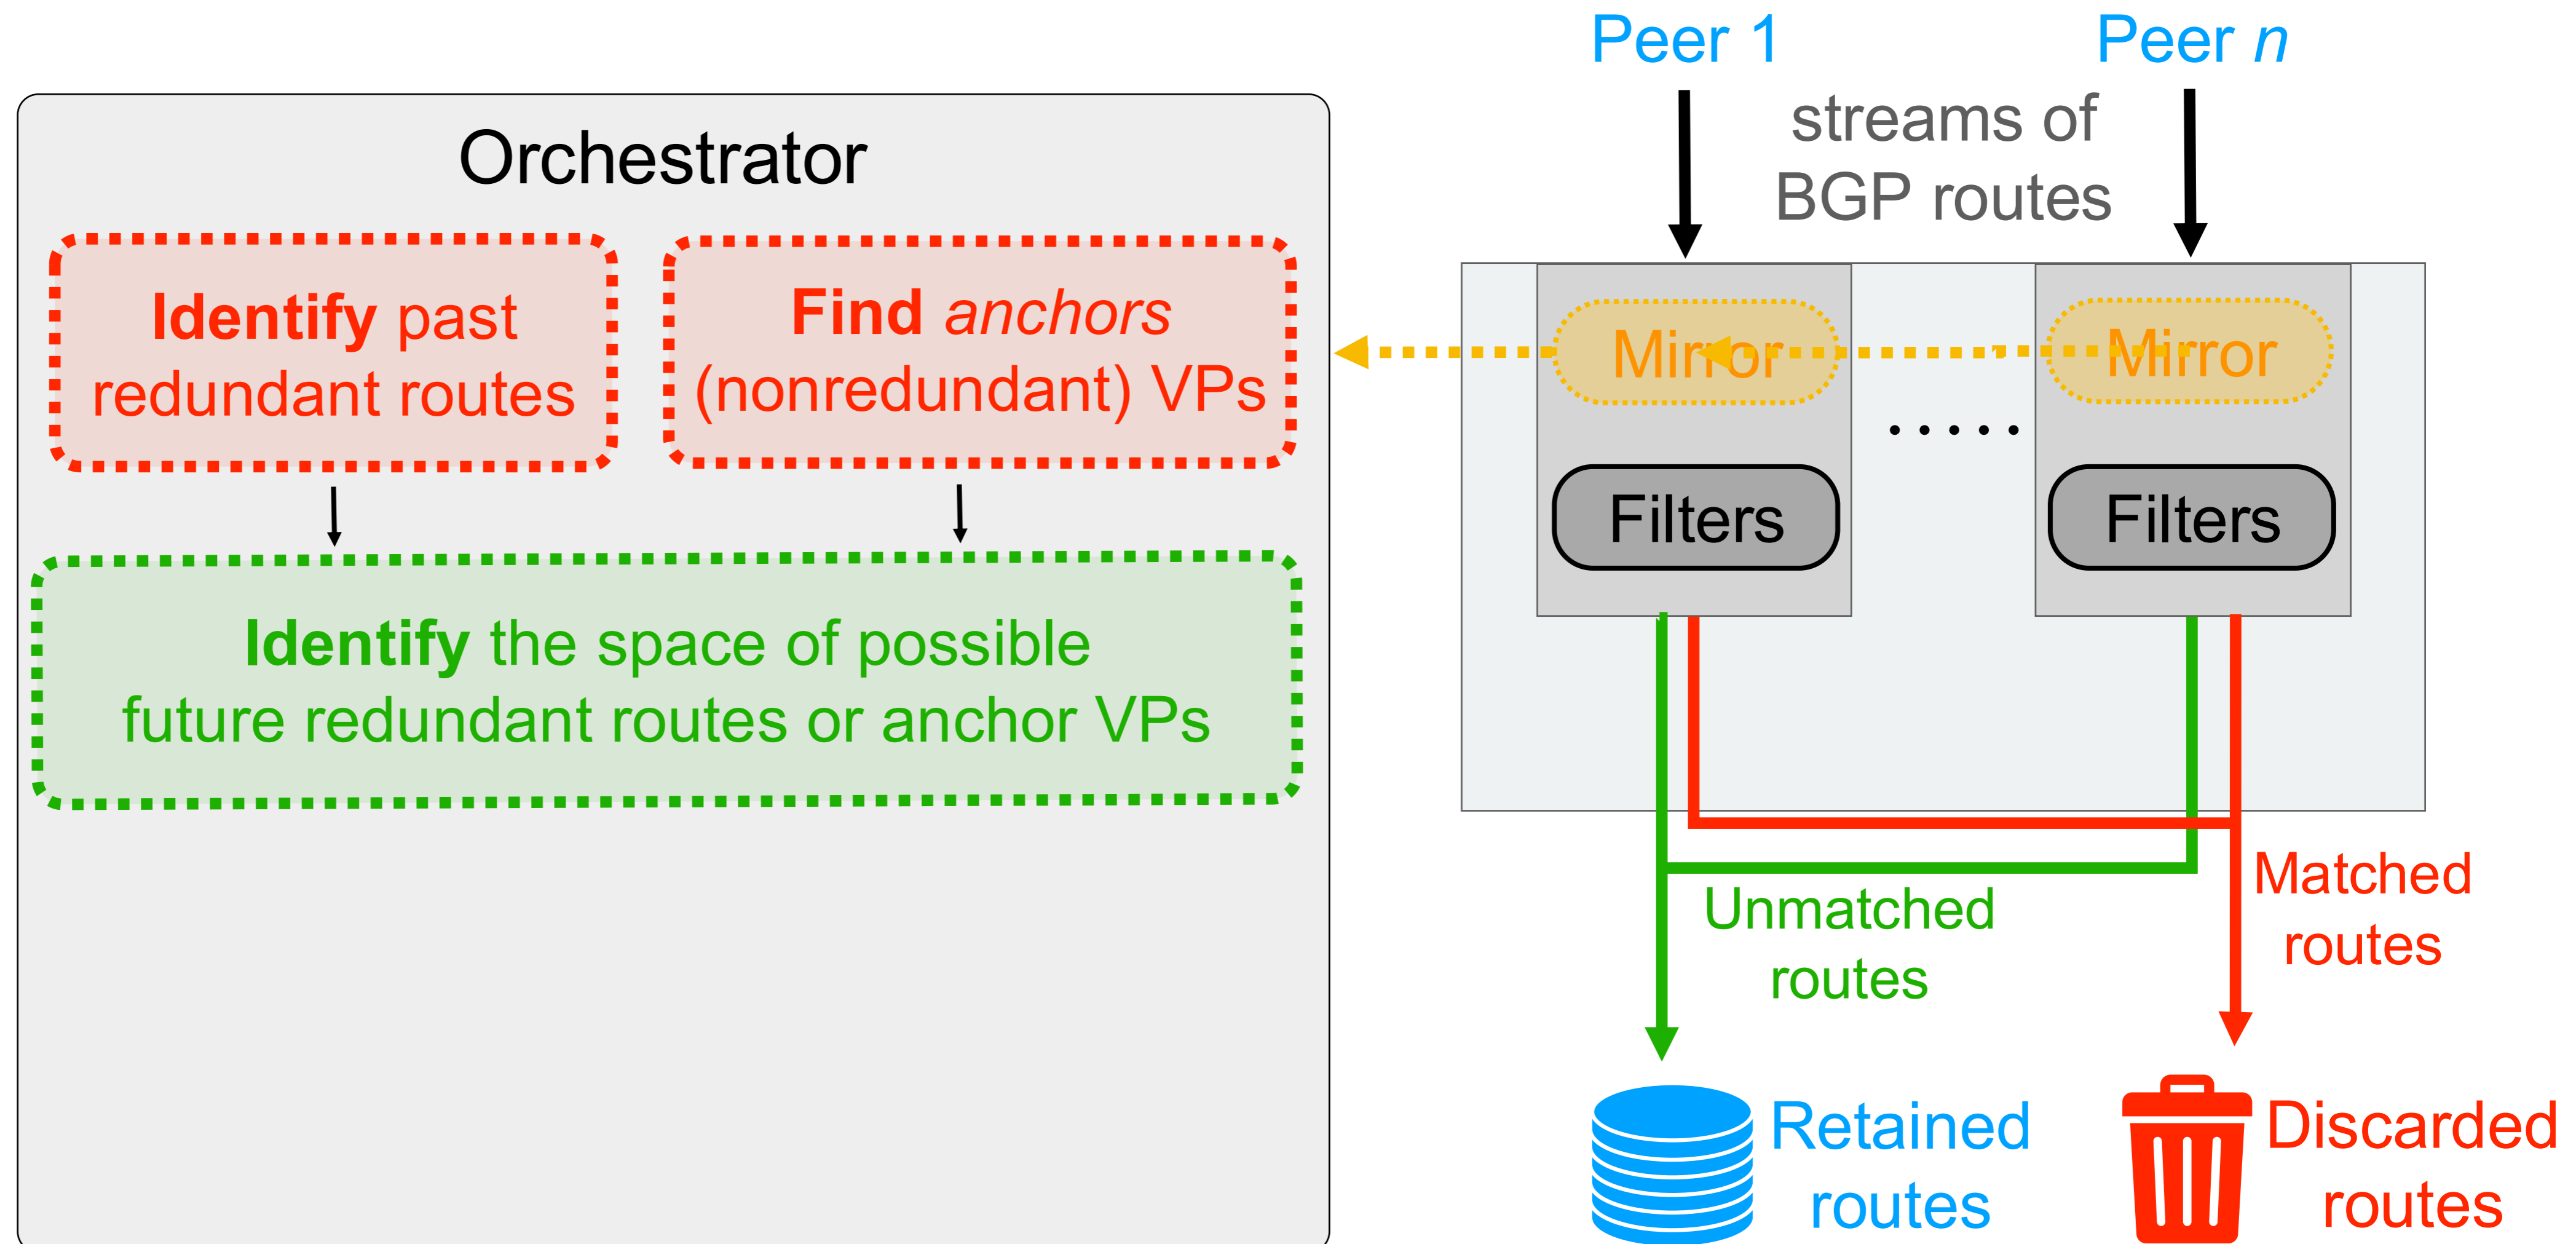

**GILL** identifies past redundant routes, predicts the future ones, and builds filters that retains only the most useful future routes

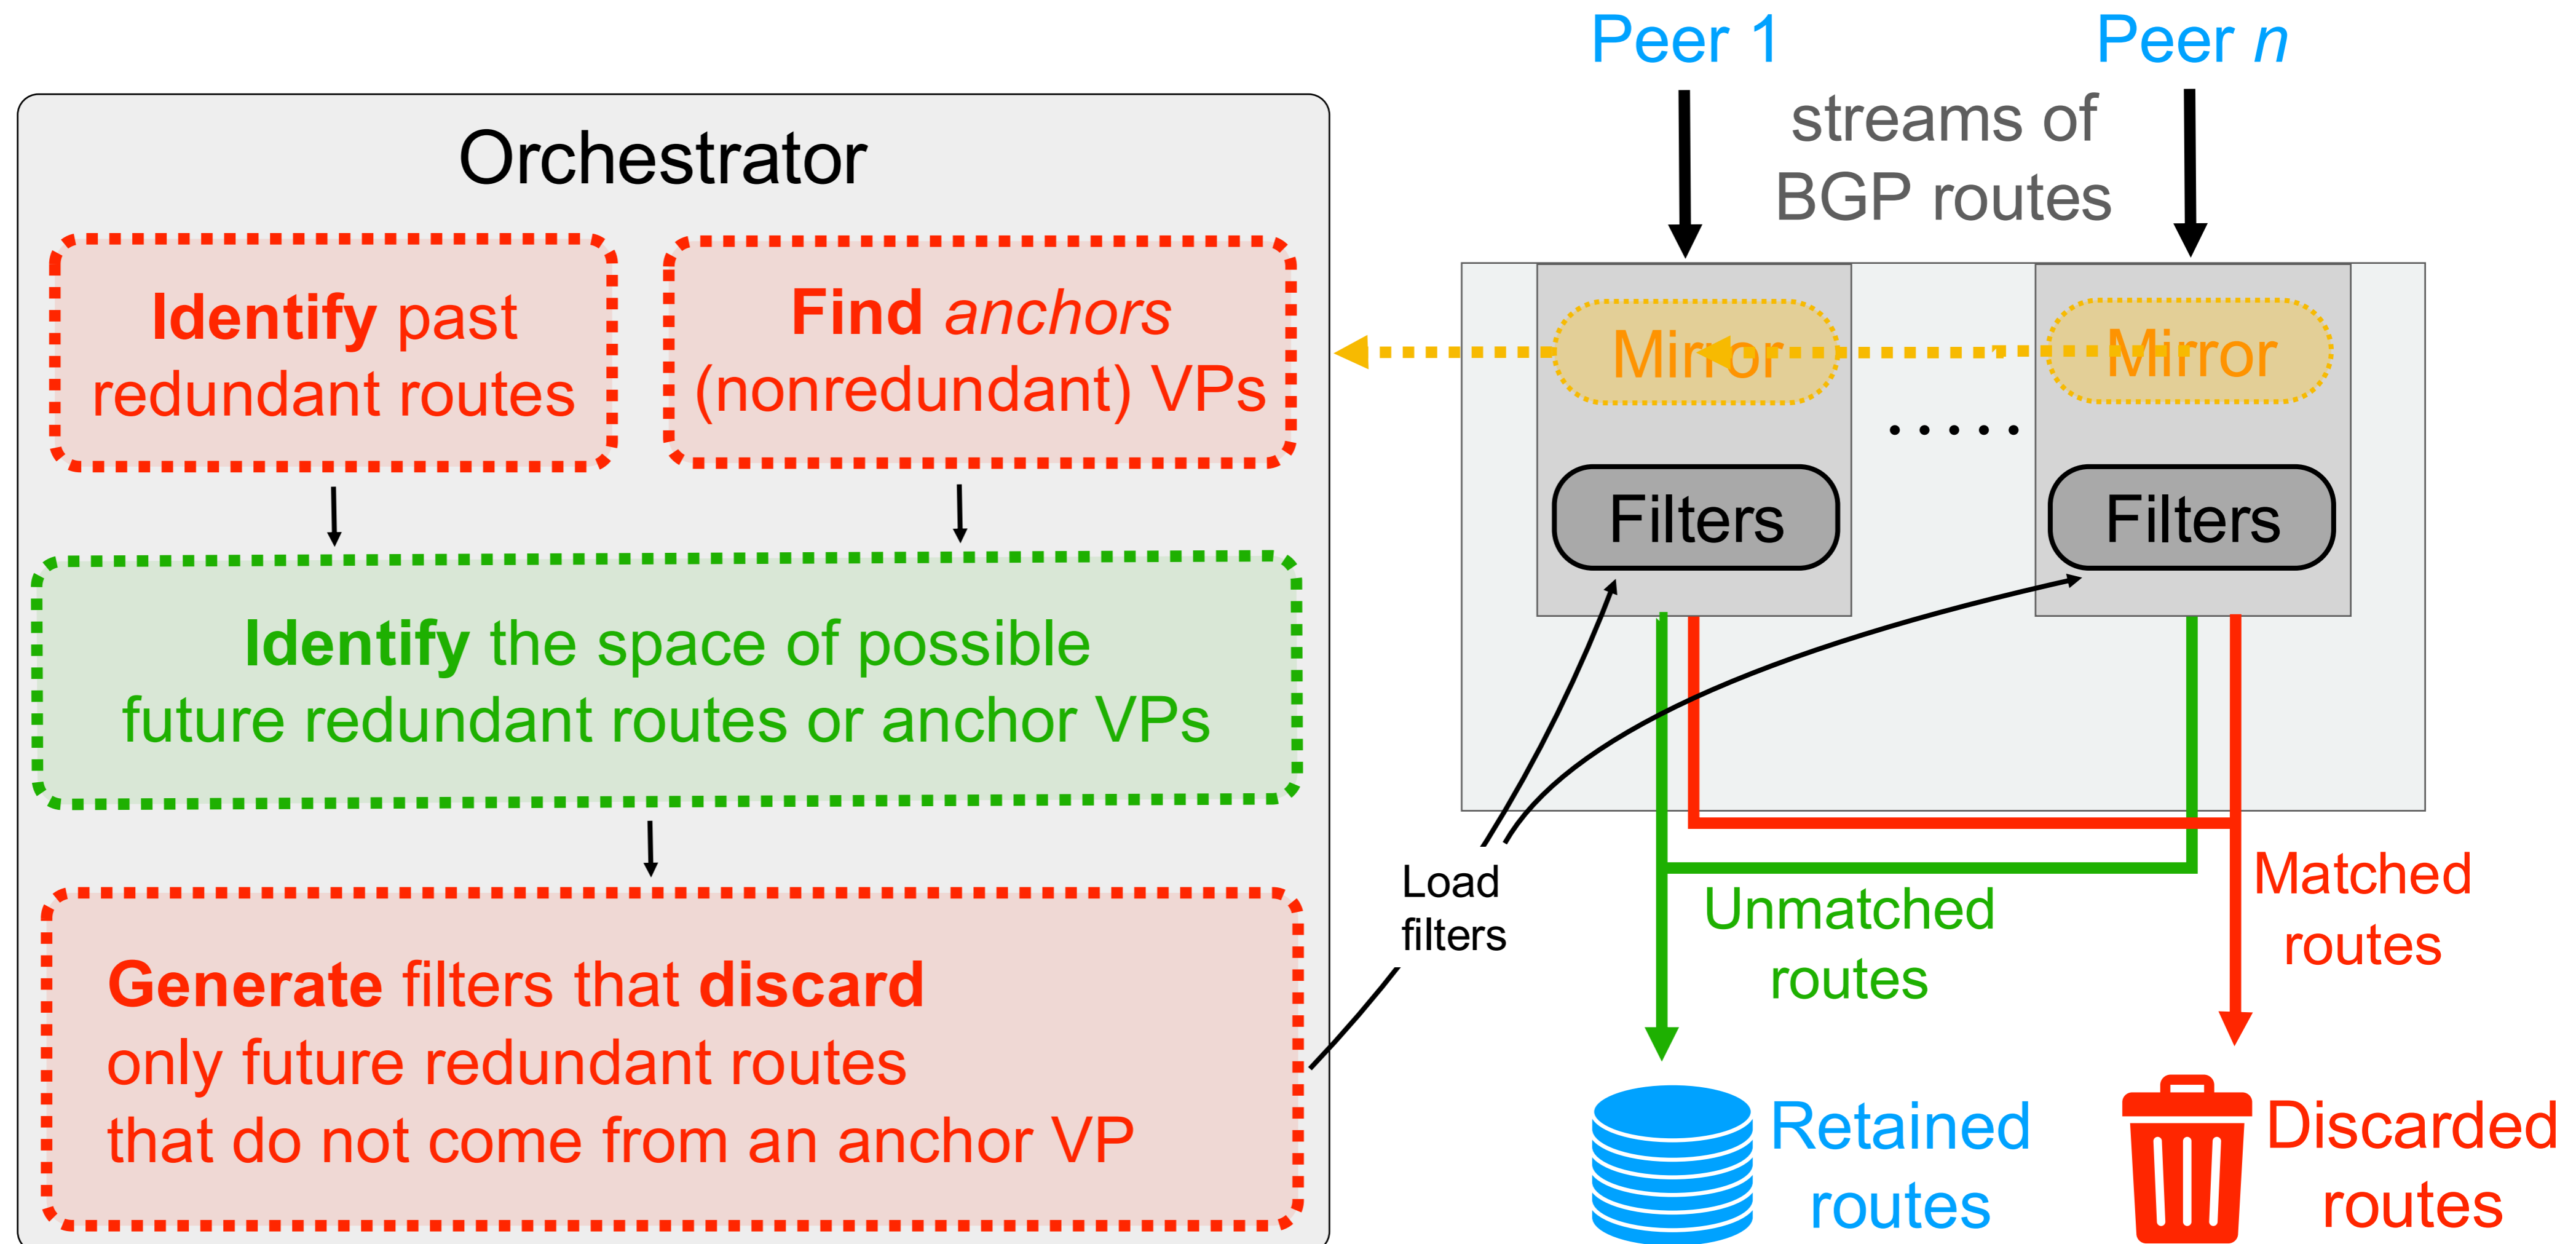

**GILL** identifies past redundant routes, predicts the future ones, and builds filters that retains only the most useful future routes

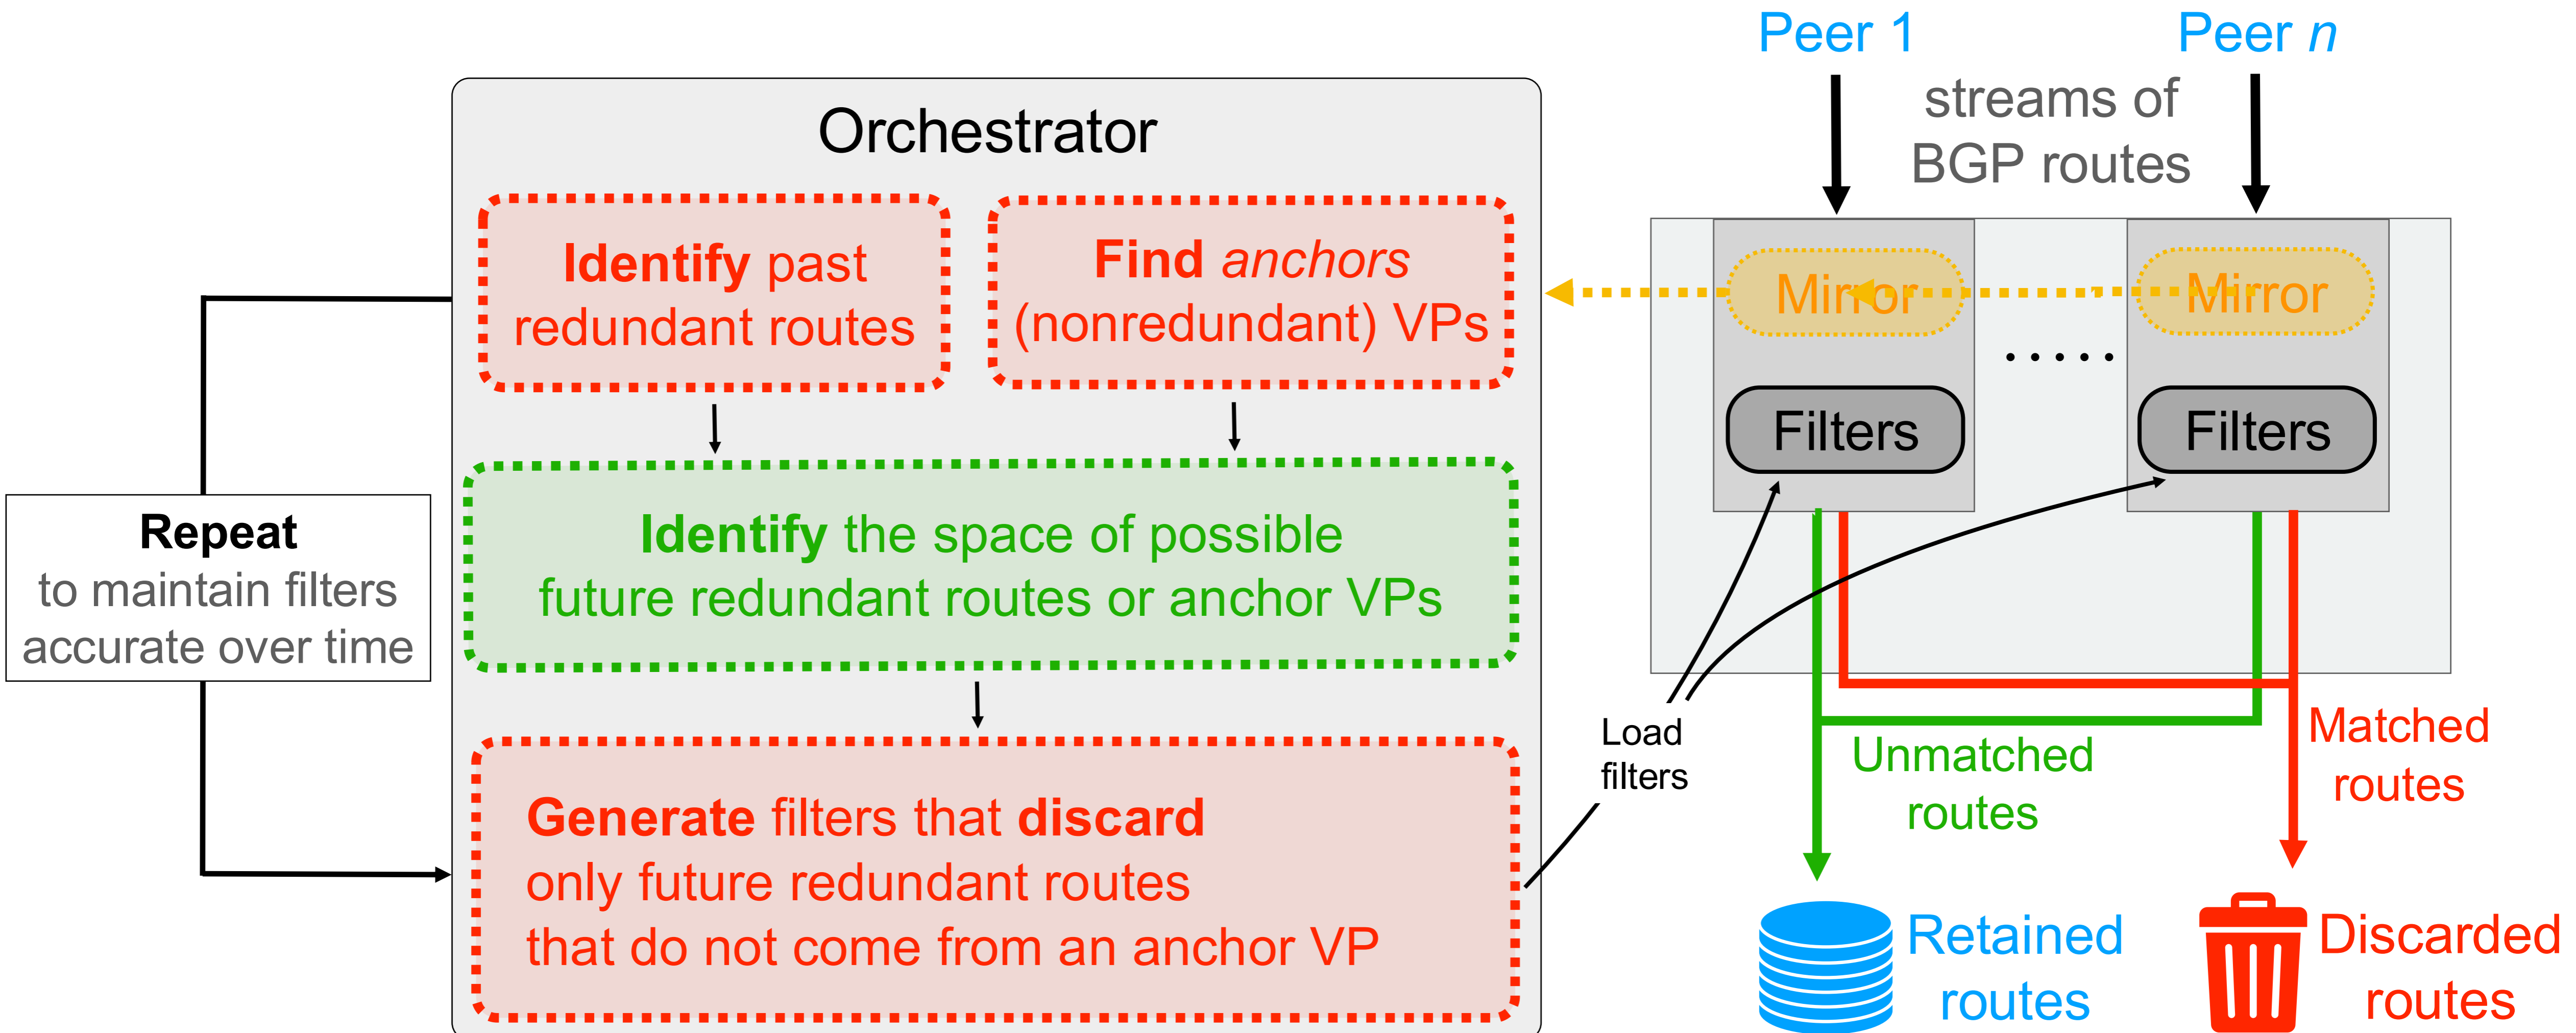

*GILL* identifies past redundant routes, predicts the future ones, and builds filters that retains only the most useful future routes
